A WAY FOR - DECEPTIONING THE NORMAL–OR THE–DANGEROUS CELLS USING VIBRATIONS

BY

Markos Georgallides

[1]Larnaca–Cyprus (Expelled from **Varosha** - Famagusta town occupied by the Barbaric Turks , in Aug - 1974) Cyprus , Civil & Structural Engineer (NATUA) , Athens . Email address : georgallides.marcos@cytanet.com.cy

Abstract :

The Electron`s Nutation in Hydrogen cave Produces Energy due to g effect , as minimum frequency $f_n \equiv 2{,}8398447.\ 10^{10}$ H and thus exists in all Atoms . This Energy of Hydrogen-Cave becomes an Electrical - Magnetic Conductor which is the Pin and Plug of atoms . Pins entering Into the other Atom-Sockets consist the Orbit-Bracket–Hooks i.e. are the Hands of Atoms . Hooks Placing their Pins into the other Atoms Drains = Holes = Plugs , is done that what we say Bonding .

Hydrogen-Cave In –Out Universe occupies mass m_H velocity $\vec{c}$ and Power P_H .

Preliminaries :

Atoms are consisted of a Hydrogens - Heap , which vibrates and Equilibrium at the Dynamic Mode-Shapes following The Stationary – In Sphere , Tetrahedron , Cube , Ex-Sphere - Geometrical construction . Since vibration means the frequencies in each Atom or and its Compound , so thus they consist the *Electromagnetic Waves* . The Interactions of any two or more Energy Systems with known Status use the Markos Program which is ⇒ { ***The Carrier Modulating–Modulated–Demodulation Waves Process***} for their Energy-Spectrum Waveform . Electromagnetic Signals may be used to Transmit Information very quickly and over great distances . Informations are encoded on Atoms - Signals using , Amplitude and Frequency modulation , and reviewed in the Program . The Process of retrieving the information from encoded Signals is detected by the Antidotes .

How to Cite:

Georgallides, M. (2025). A WAY FOR - DECEPTIONING THE NORMAL – OR THE – DANGEROUS CELLS USING VIBRATIONS. GPH-International Journal of Applied Science, 8(10), 01-118. https://doi.org/10.5281/zenodo.17607512

This simple Program- Process allows the User to detect any action of the , ***Initial – Signal*** , through the Modulating–Modulated–Demotulated Process , to the ***Final and wish Repaired Signal*** . The Spectrum Analyzer is detected in all Steps.
An Application of the method is used on CELLS which consist themselves a close System or , a Complete–Energy-Monad .
Keywords : Deceptioning the Cells using Vibrations ,

CONTENT

A...GENERAL :

1a..The Results in Hydrogen - cave :

1...Hydrogen-**Cave** , IN – OUT Universe occupies **mass** $\mathbf{m_H}$, **velocity** $\vec{c}$, and **Power** $\mathbf{P_H}$

2...**Electron** in Hydrogen-cave **Precesses** and **Nutates** due to the **Gravitational constant G , g .** The produced Work is stored in form of → **Stress Energy** as **Hydrogen – Bracket - Hook**← The Electron **Precesses** from the continuous and immense-communication to **gravity, g** .
Electron-Spin is the **Angular-momentum-vector** $\overline{B}$ and rotates according to equation $\frac{dB}{dt}$

3...The Stationary → **Tetrahedron , In-Sphere , Cube , Ex-Sphere** ←construction of **Atoms** Permits the **Space – coordinate - Structure** of Atoms ,
The **Wave-eigenfunctions** of **many non-commuting Physical operators** as Momentum . Power , from the **Quantum-Mechanical** description of the **Physical-Reality** is **Complete**

i.e. IF-known the **Physical Operators , their coordinates are** simultaneous **Physical reality**.

4...The Interactions of **Two or more Systems** with known **Status** can be calculated any time by the Bioelectronic-Spectrum of the →{ **Carrier-Modulating-Modulated , Demodulation Process Mechanism** } ← using Markos Program < **Programming Atoms-Bonding** and **Their Compounds** > **SO** ,
Energy ≡ motion is of **Wave nature** which enters the **Energy caves** and becomes a **Particle or Wave or Both** . In case of **Photons** exists this DUAL-Property , **Wave – Particle** . Thus The Historical Doubt of **Einstein - Podolsky - Rosen** for the Q-Mechanics Completion **VANISHES .** [100,104] .

5... **The** Programming of Atoms Bonding is the Quantization of ***Atoms-Wave-Energy*** to all Possible Equilibrium Positions of the [⊕↔⊖] constitutes Reactions .
The Wave-Energy as Vibration travels at 75-90 % of the light speed **c** , while the Wave-Energy in Black Holes is $n\,\pi\,c$ times of the light speed . [100-101]

6... From all the Possible Reactions in Compounds , the **Bonding or the Releasing of Energy** is the Vital rule of the Theory of Vibrations .The Program **Programming the Atoms and their Compounds** , analyses all the Interactions of two or more Energy Systems with known Status using the ,
→ **Carrier – Modulating – Modulated – Demodulation Waves Process** ←
Some following Wave`s Properties that are Defined :

6a... The Equilibrium Mode – Shapes , Φ , Diagrams .

6b1..The Circular – Frequencies , $\mathbf{W_R}$, in 10^{15} Hz ,

6b2..The Natural – Frequencies , $\mathbf{f_R}$, in 10^{15} Hz ,

6c.. The Resultant Energy – State , $\mathbf{E_R}$, in e-Volt ,

6d...The Electric–Magnetic Field , $\mathbf{E_R - M_F}$, in 10^{-12} Ampere -10^{-6} Tesla ,

6e.. The Intensity of the λ-Electric–Field , $\mathbf{I_\lambda}$, in 10^{-12} Ampere ,

6f.. The Intensity of Magnetic–Field , $\mathbf{M_\lambda}$, in 10^{-6} Tesla ,

6g.. The Wavelength , $\boldsymbol{\lambda}$, in $.10^{-10}$ meters ,

6h.. The Wave Velocity , $\bar{\mathbf{v}}$, in 10^5 meters / s ,

6i1..The Resultant Voltage at Wavelength-sides , $\mathbf{V_\lambda}$, in Volt ,

6i2..The S-Bands Voltages at Wavelength-sides , $\mathbf{V_\lambda}$, in Volt ,

6j.. The Radius of the Helical motion , $\mathbf{r = A_R}$ in $.10^{-10}$ meter ,

6k.. The Total Carrier Power , $\mathbf{P_{CT}}$, in 10^{-20} Watt ,

6l.. The Total Side-Bands Power , $\mathbf{P_T}$, in 10^{-20} Watt ,

6m..The Temperature from Voltage or K-Energy become as , $\mathbf{T_{VB}}$, in Kelvin ,

6n.. The Side-Bands Amplitude , $\mathbf{A_B}$, in 10^{-10} meter ,

6o.. The Side-Bands Coefficients , **a - m** , in n-n ,

6p.. The Modulating Phase Shift , $\boldsymbol{\varphi}$, in Rad /2π ,

6q.. The Modulating Factor , $\boldsymbol{m}$, in n-n ,

6r.. The Total Energy-Status , **a - m** , in H-W ,

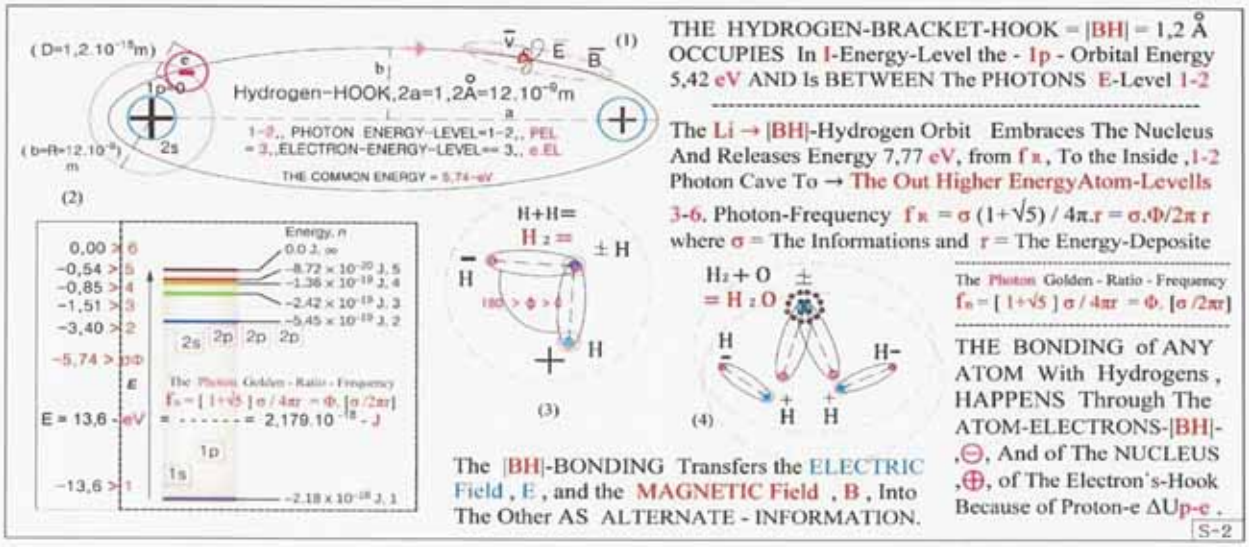

Figure-1.. The $\pm$ Energy in Hydrogen and Atoms exists from Hydrogen Common-Atom .

The two Hydrogen Bonding $\rightarrow$ $H + H = H_1^1 + H_1^1 = H_1^{1-1}\, H_{1-1}^1 = H_1^0 + H_0^1 = H_2$

Water $H_2O = O_1\, H_2 = O_2^2\, H_2^2 = T\,{}_4^4 = O_2^{2-2} H_{2-2}^2 = O_2^0\, H_0^2 = ES\,{}_{2=T/2}^{2=T/2}$, Still. [102]

B... AN TESTING - METHOD :

1b,, The Needed – Steps :

1)...We choose TATP - Explosive , of chemical formula 3.[C3 H6 O2] = [C9H18O6] which belongs to a class of Organic Peroxide explosives, and exploding violently upon Heating . We will detect its entire **JOURNEY** towards the center of the Cell with its ***Initial or Final and its Repaired – Signal*** .

2)...The Membrane ***Mediator*** (coactivator) is Thermochemical of pre-viotic as is The carbon dioxide and water of chemical formula [C O2 H] n = 6

3)...The Membrane ***Pathway - Sensor*** is Electrochemical as is the Nitrogen Dioxide of chemical formula [N O2]

4)...The Membrane ***Signaling*** is the Snare - Protein as is the Nucleic acid Hormone of chemical formula [N H3 C O O]

5)...The Plasma Intracting ***Ligand Signal*** is the endocrine Signaling as are the two Isomeric Hydrogen of chemical formula 2.[N H4] O1

6)...The Self ***Assemble Signal*** Membrane Head – Tail Bilayer as is the Phospholid of chemical formula [N P O4 H O2 O2]

7)...The ***Building Block*** of the Membrane as this is the Lipid Protein of the chemical formula O C [C H2]17 + O C [C H2]17

8)...The Polar and Flavoring ***Glues - Agent*** , the Receptors Controller as it is the Electronic Pathway of chemical formula C O H [COH]4 + [CH2OH] .

9)...The Membrane ***Lipid Protein Plasma*** as is the Glycerophospholipid of chemical formula [PO4]+[CH2]2+CHO2C2 +HO +H4 +CH3[CH2]17 + COOH + CH3 [CH2]17 + COOH

10)..The NORMAL ***or*** **DANGEROUS** Initial or Repaired Signal In-balancing the DNA as is the Dioxin d.ATP of the chemical formula 4.[C10 H12 N5 O12 P4]

11)..The **CANCEROUS** Repaired Signal In-balancing the DNA as is the Dioxin d.ATP of the chemical formula 15.[C10 H12 N5 O12 P4]

2b,, From Article [111]

1... The Resonance of 2 frequencies A , B occurs , when their Natural-frequencies coincide , **i.e.** it is valid A = B.

2... The two frequencies A , B , **are coupled** , **when** a Third frequency C is added so that A , B , are in Resonance , **i.e.** it is valid A + C = B + C.

3... When [**A**] **is** an carrier wave , [**B**] **is** the modulating wave , [**M**] = [A] + [B] , **is** the modulated wave , [DM] **is** the demodulated wave , [AN] **is** the Antidote , [**LNS**] **is** the Local Nervous System , [**CNS**] **is** the Central Nervous System , **then**

for the coupled frequencies it is valid → [M] + [AN] = [LNS] & also [M] + [AN] = [CNS] ← **That is** , the Antidotes , [**AN**] are those frequencies as the above [C] that are added **so that** [A] , [B] **are in Resonance with them** .

4...The Uncoupled values are inside of the Coupled Natural frequencies by small Amounts .The multitude of numbers of the uncoupled signaling Systems are placed to the **Sidebands** as this is the **Athwart Energy Vibration Spectrum** .

5... Placing ⇒ [M] = [A] + [B] → The Modulated Wave .
[AN] = [C] → The Antidote ,
[M] + [AN] = [LNS] → **IS in Resonance to Local Nervous System ,**
[M] + [AN] = [CNS] → **IS in Resonance to Central Nervous System.**

1f., The Flow-charge : [From Breast Total (Cannabinoid Breast Cancer)]

[M] + [AN] = [CNS] → **IS in Resonance to Central Nervous System.**

Conclusions :

1...The JOURNEY of **TATP** - Explosive , begins from the **CARRIER-WAVE** , which Is accompanied with the [(1) + (2) + (3) + (4) + (5)] Side-Band Waves , becoming from the demands of the Journey circumstances .

2...Along the Way , the CARRIER-WAVE , is attacked by attackers=Side-Band Waves ≡ [THE **MODULATING WAVE**] ≡ [(6) + (7) + (8) + (9) + (10)] , and finally becomes [THE **MODULATED** WAVE] ≡ [(1) + (2) + (3) + (4) + (5)] ± [(6)+(7)+(8)+(9)+(10)]

3...This [**MODULATED** WAVE] reaches its destination , which is the **Cell -Membrane** . At the door guard-1 asks for the entry code . Upon entering, guard-2 asks for the Pass code and at the main-door of the CELL , guard-3 asks for the Entry code in the CELL.

4a...**When in Cell** , the DNA is Normally Functioning , then **TATP** creates vapor traces. TATP is trapped within the **MODULATED** WAVE , and in order to act it needs to separate from 1-System into another 2-System in order to Act. 2-Systems are the Antidotes that contain the TATP structure .

4b... When in Cell , and DNA is Functioning with BAD-Cholesterol , then TATP creates vapor traces and in order to Act needs Antidotes that contain the , TATP structure .

4c... When in Cell , and DNA is Functioning with VERY-BAD Cholesterol , then TATP creates vapor traces and in order to Act needs Antidotes that contain the TATP ..

4d... When in Cell , and DNA is Functioning with CANSEROUS DNA , then **TATP** creates vapor traces and in order to Act needs Antidotes that contain the TATP structure , for creating vapor traces in Cell destroying the cancer.

Antidotes that contain the TATP-Explorer must Resonance with the **Modulated Wave** ,
Antidotes that contain the TATP-Explorer , with Frequency > **Mod-Wave** , are **Active** .
Antidotes that contain the TATP-Explorer , with Frequency < **Mod-Wave** are **Neutral** .

To Whom It May Concern .
Re: Article 114 by Marcos Panayiotou Georgallides

I was amazed by the details contained in the above article based on current knowledge and extrapolations inspired by the intellectual proclividies of the author.

It appears to me that further research based on the avenues that are implied by the article may lead to clinically applicable advances in chemical oncology, neurology, anesthesia and possibly other medical disciplines for the benefit of suffering humanity.

P.E Frangou

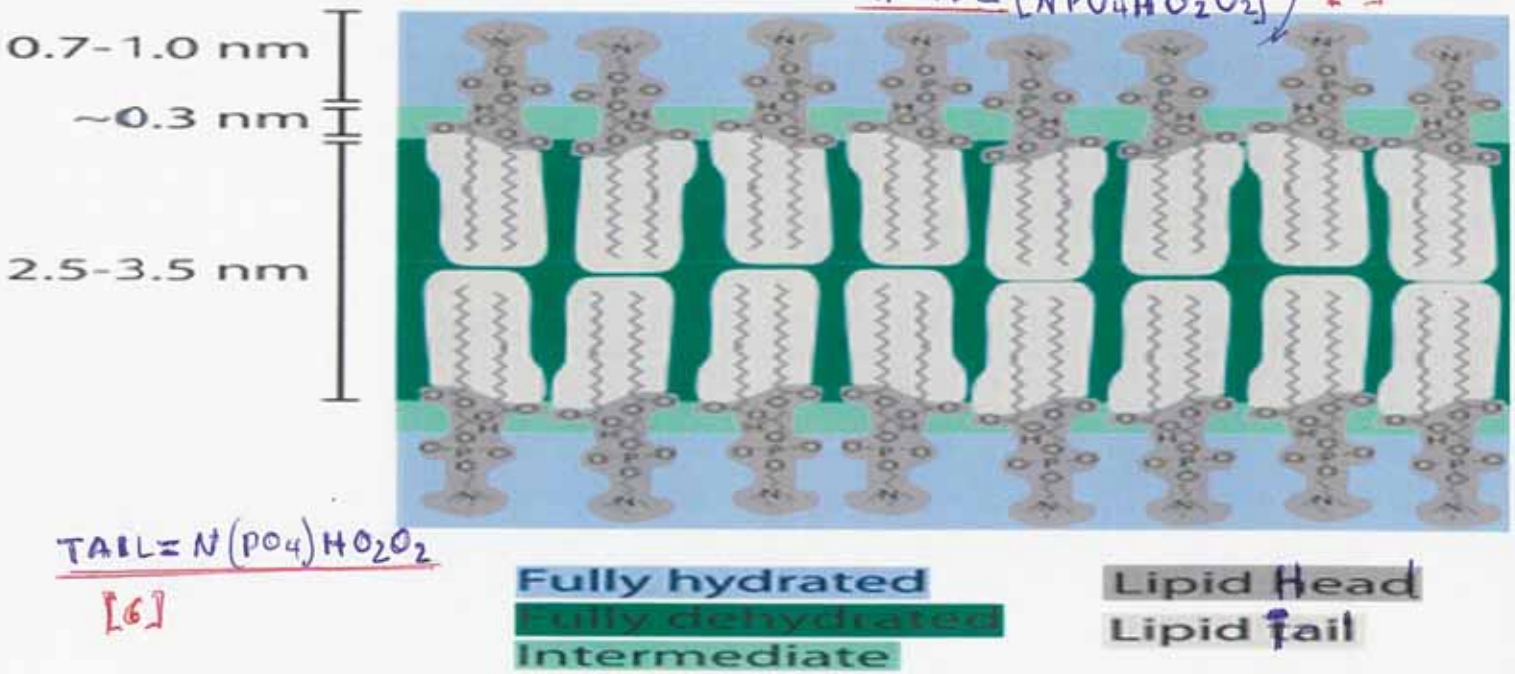
P.E. Frangou

AN MEDICAL REPORT RELATED TO ARTICLE 114-DECEPT CONCERNING THE WAY FOR DECEPTIONING THE NORMAL OR CANCERED CELLS BY VIBRATIONS

THE CELL MEMBRANE

Schematic Cross Sectional Profile of a typical lipid bilayer. There are three distinct regions: The Fully Hydrated Headgroups, the Fully Dehydrated Alkane core and a Short Intermediate Region with partial hydration. Although the Head groups are Neutral, they have significant Dipole Moments that influence the molecular Arrangement.[5]

HEAD = $[NPO_4HO_2O_2]$ [6]



TAIL = $N(PO_4)HO_2O_2$ [6]

The lipid bilayer is very thin compared to its lateral dimensions. If a typical mammalian cell (diameter ~10 micrometers) were magnified to the size of a watermelon (~1 ft/30 cm), the Lipid Bilayer making up the Plasma Membrane would be about as thick as a piece of office paper. Despite being only a few nanometers thick, the bilayer is composed of several distinct chemical regions across its cross-section.These Regions and their Interactions with the Surrounding water have been characterized over the Past several decades with X-ray Reflectometry,[6] Neutron Scattering,[7] and Nuclear magnetic Resonance techniques.[8] The first Region on either side of the Bilayer is the Hydrophilic Headgroup. This Portion of the membrane is completely Hydrated and is typically around 0.8-0.9 nm thick. In Phospholipid bilayers the Phosphate group is located within this Hydrated region, approximately 0.5 nm outside the Hydrophobic core.[9] In some cases, the Hydrated region can extend much further, for instance in lipids with a large Protein or long sugar chain grafted to the Head. One common example of such a modification in Nature is the Lipopolysaccharide coat on a Bacterial Outer Membrane.[10]

Cell signaling

Typically, the signaling process involves three components: the signal, the receptor, and the effector.[citation needed] In biology, signals are mostly chemical in nature, but can also be physical cues such as pressure, voltage, temperature, or light. Chemical signals are molecules with the ability to bind and activate a specific receptor. These molecules, also referred to as ligands, are chemically diverse, including ions (e.g. Na^+, K^+, Ca^{2+}, etc.), lipids (e.g. steroid, prostaglandin), peptides (e.g. insulin, ACTH), carbohydrates,

Ligands are Specific Receptors as the $COH+(COH)_4$ which are Glues and Flavoring Agents to the Polar Agents CH_2OH which control Receptors. [8]

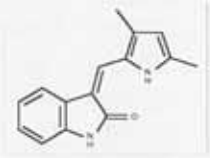
Signalling Protein = 02 CO2.

Snare Proteins = C2 Ca C2., NH3 COO., [4]

Forms of Cell Signaling

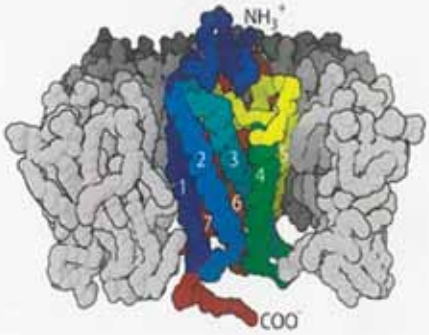
Autocrine = [CF]2 + FN + TCF

Differences between Autocrine and Paracrine Signaling



Autocrine Signaling involves a cell secreting a Hormone or chemical messenger (called the autocrine agent) that Binds to Autocrine Receptors on that same cell, leading to changes in the cell itself.[13] This can be contrasted with paracrine Signaling, intracrine Signaling, or classical endocrine Signaling.

Intracrine = [NH]2 O . [5]



In Intracrine Signaling, the signaling chemicals are Produced inside the cell and bind to Cytosolic or nuclear Receptors without being secreted from the cell. The intracrine signals not being secreted outside of the cell is what sets apart intracrine signaling from the other cell signaling mechanisms such as autocrine signaling. In both autocrine and intracrine signaling, the signal has an effect on the cell that produced it.[14]

Phospholipids [Bilayr] CELL MEMBRANES

A **Phospholipid** is a lipid that contains a Phosphate group and is a major component of cell membranes. A phospholipid consists of a hydrophilic (water-loving) head and hydrophobic (water-fearing) tail (see figure below). The phospholipid is essentially a triglyceride in which a fatty acid has been replaced by a phosphate group of some sort.

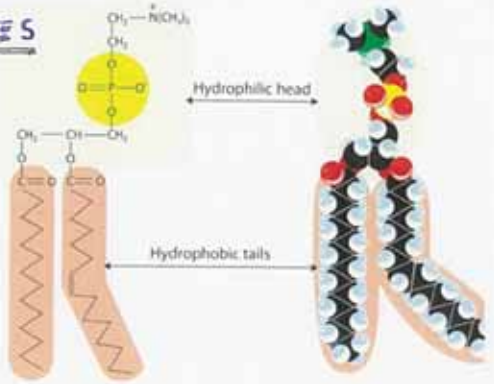

Figure 14.3.114.3.1: A phospholipid consists of a Head and a Tail. The "Head" of the molecule contains the Phosphate group and is Hydrophilic, meaning that it will dissolve in water. The "Tail" of the molecule is made up of two fatty acids, which are Hydrophobic and do not dissolve in water. **Cell - Lipids, Phospholipids, Membranes | Britannica**

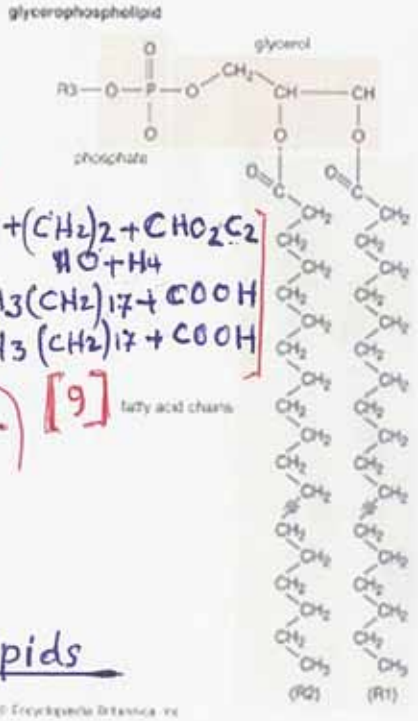
Plasma Membrane lipids - Protein [Glycerophospholipid]



1)..The formula for glycerol is $C_3H_8O_3$. It has 3 carbon (C) atoms, 8 hydrogen (H) atoms, and 3 oxygen (O) atoms. In this image, you can see the appearance of glycerol and its chemical formula and structure. The chemical structure of glycerol shows that each carbon atom is bonded to an -OH group.

Fatty acid Wikipedia

2)..Unsaturated fatty acids ; Erucic acid , $CH_3(CH_2)_7CH=CH(CH_2)_{11}COOH$, cis-Δ · 22:1, [7]

Glycerophospholipid= $OC(CH_2)_{17} + OC(CH_2)_{17}$

$PO_4 + (CH_2)_2 + CHO_2C_2$
$HO + H_4$
$CH_3(CH_2)_{17} + COOH$
$CH_3(CH_2)_{17} + COOH$
[9]

Its general formula is $C_nH_{2n}O_2$, where there are twice as many hydrogen atoms as there are carbon atoms, and there are always two oxygen atoms. Many food sources have saturated fatty acids present in them, particularly, meat, dairy and poultry.

Structure and organization of Phospholipids

When Phospholipids are exposed to water, they self-assemble into a two-layered sheet with the Hydrophobic tails pointing toward the center of the sheet. This arrangement results in two 'leaflets' that are each a single molecular layer. The center of this Bilayer contains almost no water and excludes molecules like Sugars or Salts that dissolve in water. The assembly process and maintenance are driven by aggregation of hydrophobic molecules (also called the Hydrophobic effect). This complex Process includes non-covalent interactions such as van der Waals forces , electrostatic and hydrogen bonds.[4]

Cross-section analysis-HEAD >> HYDRATED LIPID-ACID = N (PO4) H O2 O2
TAIL >> DEHYDRATED-LIPID-ACID= N (PO4) H O2 O2 [6]

The Head-Tail Communication In Cell-Membrane

Plasmodesmata (singular: **Plasmodesma**) are microscopic channels which traverse the cell walls of plant cells[2] and some algal cells, enabling transport and communication between them. Plasmodesmata evolved independently in several lineages,[3] and species that have these structures include members of the Charophyceae, Charales, Coleochaetales and Phaeophyceae (which are all algae), as well as all embryophytes, better known as land plants.[4] Unlike animal cells, almost every plant cell is surrounded by a polysaccharide cell wall. Neighbouring plant cells are therefore separated by a pair of cell walls and the intervening middle lamella, forming an extracellular domain known as the apoplast. Although cell walls are permeable to small soluble proteins and other solutes, plasmodesmata enable direct, regulated, symplastic transport of substances between cells. There are two forms of plasmodesmata: primary plasmodesmata, which are formed during cell division, and secondary plasmodesmata, which can form between mature cells.[5] Similar structures, called gap junctions[6] and membrane nanotubes, interconnect animal cells[7] and stromules form between plastids in plant cells.[8] The structure of a primary plasmodesma. CW=cell wall, CA=callose, PM=plasma membrane, ER=endoplasmic reticulum, DM=desmotubule, Red circles=actin, Purple circles and spokes=other unidentified

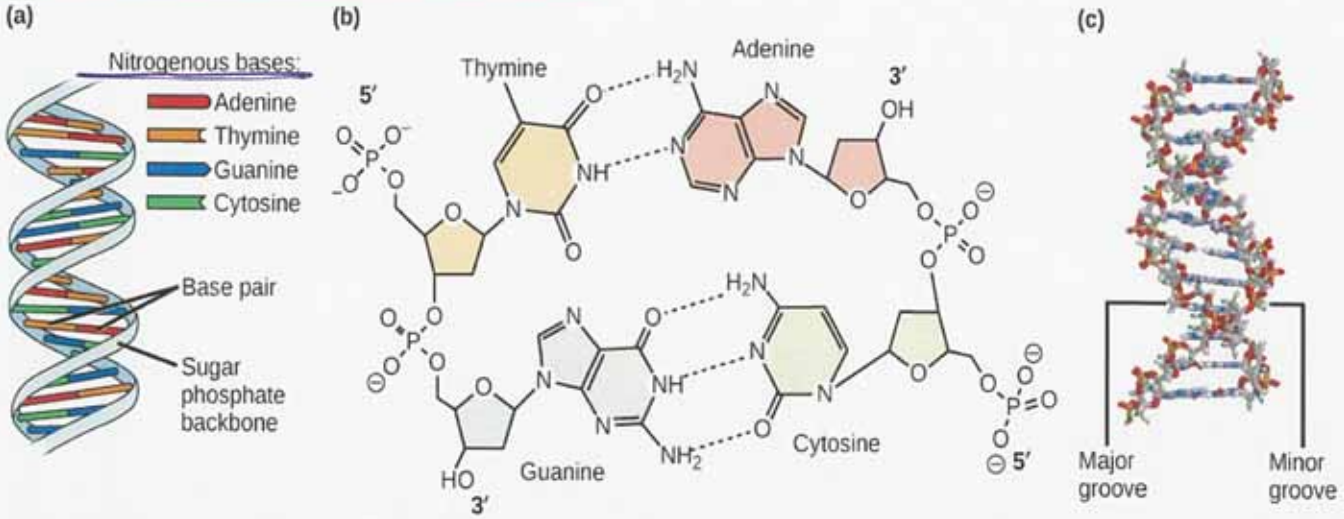
TRAPPING [An Way For Decceptioning The Dangerous Cells

1	TATP Explosive = $C_9H_{18}O_6 = (C_3H_6O_2)_3$ → The tranpozted Substa Into the Dangerous cell
3	Nitrogen-Dioxide Sensor = NO_2 → An Electrochemical Sensor.
2	Cells mediator $(CO_2H)_{n=6}$ → An Membrance mediator.
4	Signalling Protein = NH_3COO → A Snare Signal on Membrane
5	INtracting Ligand = $(NH_4)_2O$ → An Inner Signal in Plasma
6	Self Assembre Phosphalid = $[NPO_4H_2O_2]$ → An Head-Tail Signal Bilaye
7	Membrance Lipid-Protein = $OC(CH_2)_{17} + OC(CH_2)_{17}$ → Building Blocks of Membran
8	Flavoring and Polaragents = $COH + (COH)_4 + CH_2OH$ → Glues and Polar flavoringage
9	Membrancce Plasma = $PO_4 + (CH_2)_2 + CHO_2C_2 + (H_4 + H_4) + [CH_3(CH_2)_{17}COOH] +$
	The Cell-Membrance Regulates the Movement of Substomees → $[CH_3(CH_2)_{17}COOH]$
10	Imbalancing DNA = 2ATP = $[C_{10}H_{12}N_5O_{12}P_4 7.5$

The DNA Double Helix



Nucleotide Structure Review

Recall some basic structural features of the nucleotide building blocks of DNA including: the nucleotides start as off as nucleotide triphosphates. Nucleotide are composed of a nitrogenous base, deoxyribose $C_5H_{10}O_4$ (5-carbon sugar), and a phosphate group 4.[P O4] . The nucleotide is named according to its nitrogenous base, purines such as adenine (A) and guanine (G), or pyrimidines such as cytosine (C) and thymine (T). Recall the structures below. Note that the nucleotide Adenosine triphosphate (ATP)= Adenosine Triphosphate | C10 H16 N5 O13 P3 | CID 5957 Is a precursor of the deoxyribonucleotide (dATP) = Deoxyadenosine triphosphate | C10 H16 N5 O12 P3 or H12 which is incorporated into DNA. Ribose is a simple sugar and carbohydrate with molecular formula $C_5H_{10}O_5$ and the linear-form composition $H-(C=O)-(CHOH)_4-H$. The naturally occurring form, d-ribose, is a component of the ribonucleotides from which RNA is built, and so this compound is necessary for coding, decoding, regulation and expression of genes. By contrast, it is very high melting (with decomposition), insoluble in organic solvents, and a million times weaker as an acid than ordinary carboxylic acids . It is a key Nucleotide used in DNA Synthesis and Replication Deoxyadenosine-Tritosphate = $C_{10}H_{12}N_5O_{12}P_4$ in 2-5 Times more is toxic Effect. and can Significally Impact. the activity of Ribonucleotide reductase (RNR), and imbalancing the (Deoxy) pools dATP = [$C_{10}H_{12}N_5O_{12}P_4$] and For 5 dATP = Imbalances DNA [10]

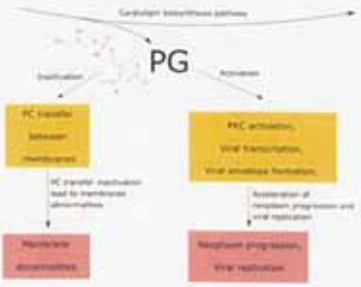
Lipid composition of the cancer cell membrane

Phosphatidic acid (PA) = P(HO)2 + O2 + O2

Phosphatidylglycerol (PG) (PA)= OH OH + PHO(O)3 +O2 +O2

Phosphatidylglycerol structure consists of phosphatidic acid bound to glycerol substituent (*Yeagle* 2016). The lipid is an anionic intermediate of the cardiolipin biosynthesis pathway (*Yeagle* 2016). Although phosphatidylglycerol comprises only about 1 mol% of the membrane phospholipids, it remains an important component of the cytosolic side of the plasma membrane due to its ionic properties (*Zech et al.*, 2009). Oleic and palmitic acid moieties are the most common glycerol substituents for phosphatidylglycerol (*Zech et al.*, 2009).

Certain studies have demonstrated that phosphatidylglycerol accounts for protein kinase C (PKC) activation and that it is involved in viral transcription (*Bailey et al.*, 2017; *Hirai et al.*, 1992; *Murray and Fields*, 1998). Moreover, phosphatidylglycerol participates in viral envelope formation (*Sands and Lowlicht*, 1976). At the tissue level, phosphatidylglycerol can inhibit phosphatidylcholine transfer between membranes, which results in membrane structure and function irregularities (*Wirtz et al.*, 1976). The importance of this compound during viral infections may suggest that its abnormal levels could be observed in virus-associated cancers such as cervical cancer (*Preetha et al.*, 2005). These fluctuations may lead to an increase in viral replication effectiveness and cell neoplasia (Fig. 3).

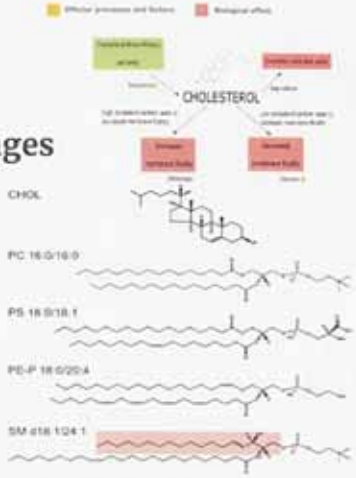


Membrane Cholesterol

Healthy = C23 H46 O H

Cancerous = 10.[C23 H46 O H]

The role of lipid species in membranes and Cancer-related changes



Illustrations of some lipid structures. Cholesterol is shown on the top followed by PC16:0/16:0, an example of a phospholipid with two saturated fatty acyl chains, which although much used in model membranes is not very common in biological samples. PS 18:0/18:1 is an example of a phospholipid with one saturated and one unsaturated fatty acyl chain, which is a very common combination, and this PS species is the most common PS species in many cells. Note that the unsaturated fatty acyl chains most often are found in the *sn-2* position and that all double bonds in phospholipids are in a *cis*-configuration

CHOL= HHHHH OH ,PC16= NO2O2+PO4+N,PS18=HO2O2+PHO(O)3+NNH2OOH,

PE18= HO3+PHO(O)3 + NH2 , SM= H(HCN)NHO +PO4+N ,

Smoking increases the risk of high cholesterol and is associated with changes in cholesterol levels, specifically affecting the "good" HDL cholesterol and the "bad" LDL cholesterol. The chemical formula for cholesterol remains unchanged: C27H46O.

The Demodulated FM - Waveform

The Antidote Was Detected from Program. The TATP with the Local. Isoleucine. Continuous the Normal Functioning of the System.

The Antidote. Succeeds the Exact Resonance of the System.

The Antidote is Consisted from the Element by Carrier-Wave which is fully Resonated with the Modulated Elements [1] + Non Polar Isoleucin

Conclusion.

TATP-Explosive Enters The Cell

1) By Ascending on the Carrier Wave
2) By Combining with the Antidote Resonant and the N-Frequency of the Nucleus

Compound

Description	6 - TATP Exp;osive = [C9 H18 O6] + NEW Anticancer-Antidote = 23.[N3 O2 C H6]
Formula	$N_{69}O_{46}O_6C_{23}C_9H_{138}H_{18}$
Total Number of Elements	309
Stiffness Factor	828

6 - ANTIDOTE ENCOTING EXPLOSIVE [1] + NEW ANTICANCER

Compound

Description	SYMEWN - PRALSETINIB- ANTIDOTE = 29.[C27 H32 F N9 O2]
Formula	$C_{783}H_{928}F_{29}N_{261}O_{58}$
Total Number of Elements	2059
Stiffness Factor	25056

The 29-Dose of Hemotherapy Antidote Pralsetinib-NEW allows the continuous feeding of Drug to Cancerus CELLS

Properties

#	Number	Symbol	Mass	Total Mass	Pins	Sockets	Bonded	Unbonded
1	783	C	12	9396	3132	3132		
2	261	N	14	3654	783	783		
3	928	H	1	928	928	928		
4	58	O	16	928	116	116		
5	29	F	19	551	29	29		

Bond - Mode

$$C^{\frac{313}{2}}\ N^{\frac{783}{783}}\ H^{\frac{928}{928}}\ O^{\frac{116}{116}}\ F^{\frac{29}{29}}\ T^{\frac{498}{8}} = \frac{498}{8}$$

The 2-only elements groups Act separately each other with strong frequencies $W_R + W_{2-3}$

Matrices

Antidote (Drug Pralsetinib NEW) is steady Acting on the MODULATED-CANCERUS-SYSTEM By Increasing or Decreasing the following:

1... From Voltage Transformers Chemical Synthesis $V_{M1} \cdot i_2 = V_{MA} \cdot i_{2A}$ increases the flow of Energy more than 20 times.

2... The high Modulated Power $P_{RF} = 1,03.10^{-20}$ W Decreases to $0,0018593.10^{-20}$ watt or 554 times less Power.

3... From the 11 Groups of Elements Decreases to 4 Group Elements, or from $W_R = 18,35.10^{15}$ Hz to $W_{R4} = 74,49.10^{15}$ Hz and Increases from $f = 0,614.10^{15}$ Hz to $11,85.10^{15}$ Hz

4... By increasing the Temperature from 414 Kelvin to 5091 Kelvin, or 12 times more, the Antidote Activates its Resonance from its frequencies. By coupling to the Signalling Modulated Concerous System. TO the continuous feeding of Drug.

Common Mass M = m x 982.8901734 kg

The Antidote (Drug EU-Gisplatin) is a steady and Continously acting on the MODULATED CANCEROUS-SYSTEM. by Increasing or. Decreasing the followings

1... From Voltage Transformers Chemical Synthesis $V_{M1} \cdot \dot{Z}_{M1} = V_A \cdot \dot{Z}_A$ Increases. the flow Energy from $2,62.1,07 = 2,80.10^{-12}$ A to. $30,014.4,693 = 140\,855.10^{-12}$ A more than 50 ti

2... The high Modulated Power $P_{RF} = 1,0346.10^{-20}$ W Decreases to $0,00077.10^{-20}$ W or. 1370 times less Power

3... From the 11 Groups of elements Decreases to 4 Groups Elements, and or. from. Frequency $W_M = 3,988.10^{15}$ Hz. To. that. increases to $W_{ANT} = 45,600.10^{15}$ Hz. by coupling to the Cancerous Signalling Syste

4... By Increasing the Temperature from 414 Kelvin to. 3116 Kelvin. or 753 times more, The Antidote Activate its. Resonance to the Signalling and. Modulated Cancerous System to the continous feeding of the Drug

5... From reaction $LC = \left(\frac{1}{W_A{}^2}\right) = 480,9172.10^{-24}$ and by $L = 10^{-19}$ H then $C = \left(\frac{1}{L W^2}\right) = 480,9178\,10^{-5}$ Farad. capable at the circuit's Resonance frequency.

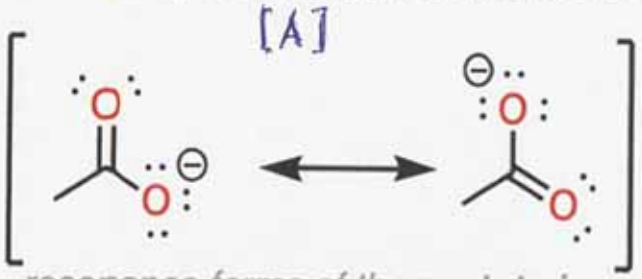
Summary: Introduction to Resonance

Structural formulae of molecules with pi bonds (multiple bonds) do not always show the **full picture** of electron density in a molecule.

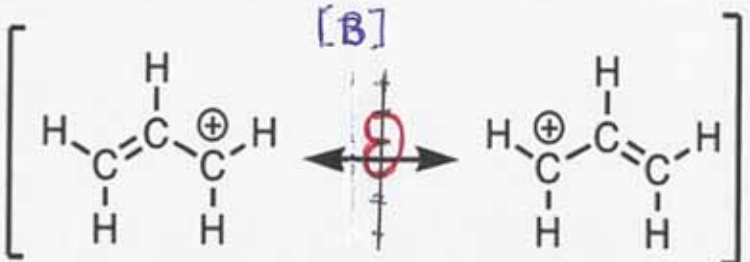
• This is because there can be more than one valid way of drawing the arrangement of pi bonds in molecules. These different arrangements of pi electrons are called **resonance forms** and are denoted with a **double sided arrow** ↔

[A]



*resonance forms of the **acetate ion**, $CH_3COO(-) = CH_2CH<O_2$*

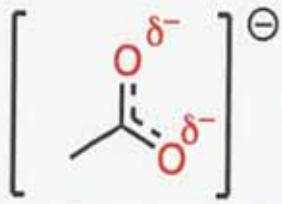
[B]



*resonance forms of the **allyl cation**, $CH_3CH=CH_2(+) = CH_2CHCH_2$*

• Importantly this is not an equilibrium. **They do not "interconvert" back and forth.** It's just that the true electron density of the molecule cannot be depicted by just one line diagram.

• If this is true, then what **is** the "true" structure of the molecule?
In these cases, the true structure is a hybrid of both of these resonance forms

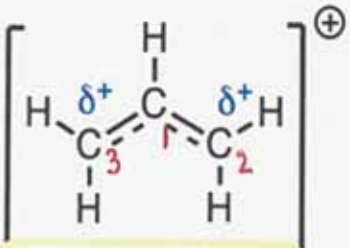


resonance hybrid

CH_3COO

C–O in acetate ion: **1.26 Å**

Intermediate between C–O (1.36 Å) and C=O (1.21 Å)



resonance hybrid

C–C in allyl cation: about **1.38 Å**

Intermediate between C–C (1.52 Å) and C=C (1.30 Å)

• The bond lengths are intermediate between those of a single and a double bond, and the charge densities on the atoms are half of those of a typical ion

• Although these cases the two resonance forms are equally important, this will not always be the case. We will shortly see examples where certain resonance forms are more important than others and the hybrid is an **unequal** weighting of resonance forms.

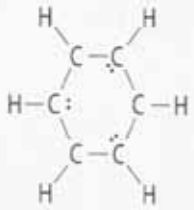
[C]

The Benzene Resonance Structure

Example 44: Benzene



Benzene is a common organic solvent that was previously used in gasoline; it is no longer used for this purpose, however, because it is now known to be a carcinogen. The benzene molecule (C6H6C6H6) consists of a regular hexagon of carbon atoms, each of which is also bonded to a hydrogen atom. Use resonance structures to describe the bonding in benzene.

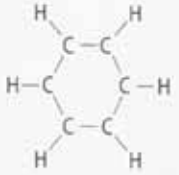
Given: molecular formula and molecular geometry , **Asked for:** resonance structures

Strategy:

A. Draw a structure for benzene illustrating the bonded atoms. Then calculate the number of valence electrons used in this drawing.

B. Subtract this number from the total number of valence electrons in benzene and then locate the remaining electrons such that each atom in the structure reaches an octet.

C. Draw the resonance structures for benzene.



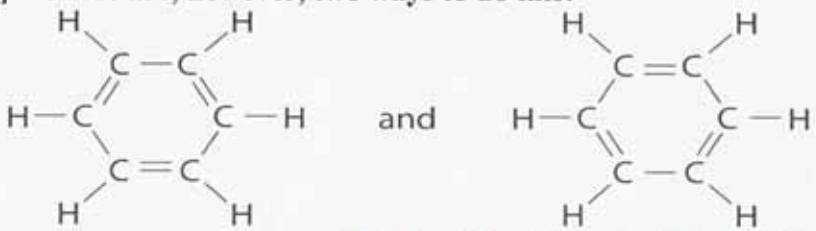
Solution:

[A] Each hydrogen atom contributes 1 valence electron, and each carbon atom contributes 4 valence electrons, for a total of $(6 \times 1) + (6 \times 4) = 30$ valence electrons. If we place a single bonding electron pair between each pair of carbon atoms and between each carbon and a hydrogen atom, we obtain the following:

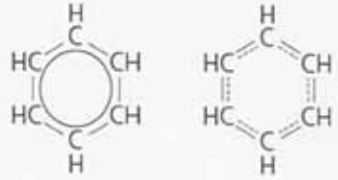
Each carbon atom in this structure has only 6 electrons and has a formal charge of +1, but we have used **only 24 of the 30 valence electrons. [B] If the 6 remaining electrons are uniformly distributed pairwise on alternate carbon atoms, we obtain the following:**

Three carbon atoms now have an octet configuration and a formal charge of −1, while three carbon atoms have only 6 electrons and a formal charge of +1. We can convert each lone pair to a bonding electron pair, which gives each atom an octet of electrons and a formal charge of 0, by making three C=C double bonds.

[C] There are, however, two ways to do this:



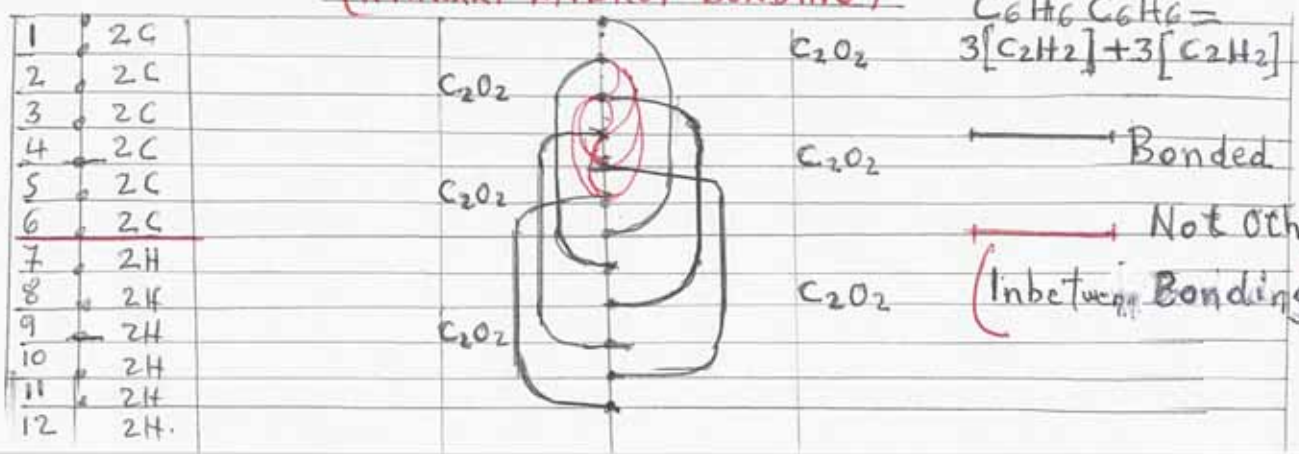
and



THE MODE OF RESONANCE

Each structure has alternating double and single bonds, but experimentation shows that each carbon–carbon bond in benzene is identical, with bond lengths (139.9 pm) intermediate between those typically found for a C–C single bond (154 pm) and a C=C double bond (134 pm). We can describe the bonding in benzene using the two resonance structures, but the actual electronic structure is an average of the two. The existence of multiple resonance structures for aromatic hydrocarbons like benzene is often indicated by drawing either a circle or dashed lines inside the hexagon:

(ATHWART ENERGY BONDING)

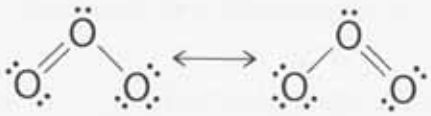


[4]

THE OZONE CHEMICAL RESONANCE STRUCTURE

out, however, that both O–O bond distances are identical, 127.2 pm, which is shorter than a typical O–O single bond (148 pm) and longer than the O=O double bond in O_2 (120.7 pm).

Equivalent Lewis dot structures, such as those of ozone, are called resonance structures. The position of the *atoms* is the same in the various resonance structures of a compound, but the position of the *electrons* is different. Double-headed arrows link the different resonance structures of a compound:



The double-headed arrow indicates that the actual electronic structure is an *average* of those shown, not that the molecule oscillates between the two structures.

When it is possible to write more than one equivalent resonance structure for a molecule or ion, the actual structure is the average of the resonance structures.

The electrons appear to "shift" between different resonance structures and while not strictly correct as each resonance structure is just a limitation of using the Lewis structure perspective to describe these molecules. A more accurate description of the electron structure of the molecule requires considering multiple resonance structures simultaneously.

Figure 1:

Early phase of axon degeneration can appear in different forms.(A) Established programs of axon degeneration (such as Wallerian degeneration or focal acute axonal degeneration) are calcium-dependent and are finally characterized by the following sequence of events: Initial injury trigger leads to an abnormal calcium influx through mechanochannels/nanopores (1) and calcium release from internal calcium stores, such as mitochondria and axoplasmic reticulum (2). The increase in intra-axonal calcium level activates calcium-dependent calpain proteases (3) that lead to cytoskeletal breakdown and eventually cargo accumulation (4), such as mitochondria and NMNAT2. (B) Astrocytopathy-driven axonal beading has characteristics that distinguish it from the other described pathways. After the lytic depletion of astrocytes (1), a sodium influx-related osmotic challenge (2) induces remodeling of the microtubular cytoskeleton (3) in the initial state without overt cargo accumulation (4). The described processes affect both myelinated and non-myelinated axons. However, for better readability of the figure, the myelin layer has been omitted in the inset illustrations. Synopsis

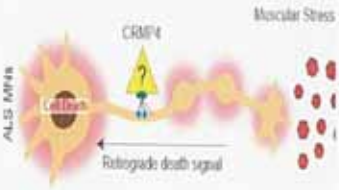
Identification of an intracellular mechanism that mediates Motor Neuron (MN) death in Amyotrophic Lateral Sclerosis (ALS) . CRMP4 Binds the Motor Protein Dynein = [C3N3O2SH10F2] + [C3N3O2SH10F2] and Transports from distal Axons to the Soma where it Promotes MN Death. Blocking the CRMP4-Dynein interaction reduces MN Death in Human-derived MNs (C9orf72) and in ALS mice. CRMP4= [C34 H47 N1 O11].Protein level is altered along ALS diseased Motor unit. Dynein mediates CRMP4 mislocalization in Motor Neurons via specific CRMP4 motif.

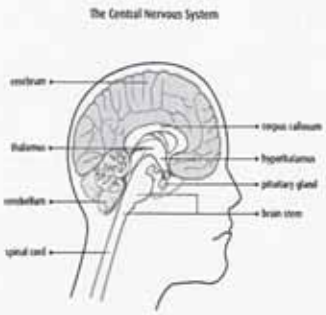
CRMP4-Dynein complexes are enhanced in ALS diseased MNs.

CRMP4-Dynein complex formation facilitates selective Neuronal loss in ALS.



Molecules Able to Regenerate the Central Nervous System

Parts of the Brain Involved with Memory,{ Aphasia }



Change that's good for the Brain

The Process of Learning something has an effect on the Brain similar to the one exercizing has on the Muscles. If we make them move, they increase in size and become stronger. The same thing happens to the Brain. By Putting it to work, we're making it alter its Structure, while at the same time improving certain functions. Because language learning is such a complex Process, the Brain regions involved in it are enhanced. This is reflected in an increase of White and Gray matter (that contains most of the Brain's Neurons and Synapses) in said regions.

Melatonin released in the Brain at night Controls the **Sleep–Wake cycle in cycle Vertebrates.** The Prefrontal Cortex (PFC) **IT IS the Part of the Neocortex that sits at the very front of the Brain. It is the most recent addition to the mammalian Brain, and is involved in many complex Cognitive functions. Human Neuroimaging studies using (MRI) machines show that when People Perform tasks requiring them to hold Information in their Short-Term Memory, such as the location of a flash of light, the PFC becomes active. There also seems to be a functional separation between Left and Right sides of the PFC: the Left is more involved in Verbal working memory while the right is more Active in spatial working memory, such as Remembering where the Flash of light occurred.**

In Humans, the Cerebellum [AR]= [C O F N3 H2], Plays an important Role in Motor Control.
Acetylcholine (ACh)= [C7 H16 Cl N O2]=12,14.10^15Hz — 7,98.eV Neurotransmitter for Memory

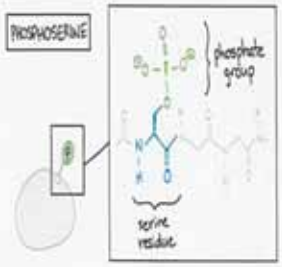
What is Aphasia? It's a Symptom of damage to the Parts of the Brain that control Language.

Types of Signal Transducing Messengers

1. **First Messengers** •Agonists(i.e. **H**ormones, **N**eurotransmitters, **P**harmacological Agonists)
2. **Second Messengers** • Molecules that Transmit Signals Received at Receptors (i.e., cAMP, cGMP, DNA Binding, ions)
3. **Third Messengers** • (i.e., Ions, Protein kinases)

1=Hormones ,N,P→Cholesterol = [C27OH46],Testosterol = [C2 O2 H7] ,Estadiol = [C1 O2 H5]
Melatonin = [C2 O2 N2 H8] , Serotonin = [C10 O1 N2 H12] ,Amino Acid = [C3 O3 N2 H8] , Dopamine = [C8 O2 N1 H11] ,Isoptoterenol = [C11 H17 N1 O3] ,Phenyleprine = [C9h13 N O2]

2=Molecules cAMP=**AMP** = [C10 H14 N5 O7 P] , **GMP** = [N5 O7 H5 P] ,
DNA-Ions = [C15 H31 N3 O13 P2]



First Messengers are extracellular signaling molecules such as Hormones or Neurotransmitters that bind to cell-surface Receptors and activate intracellular signaling Pathways. Since these molecules cannot Physically cross the Cell-membrane, they Rely on Second Messengers to Propagate and Amplify the Signal within the cell. **Second Messengers** are non-Protein intracellular signaling molecules that Relay extracellular signals received at Receptors to target molecules within the Cytosol. Common Second messengers include Calcium, Cyclic **AMP** = [C10 H14 N5 O7 P] , cyclic **GMP** = [N5 O7 H5 P] , inositol Trisphosphate (IP_3) and Diacylglycerol (DAG). [**DAG**]= P.[N4O4H4 +PO4]

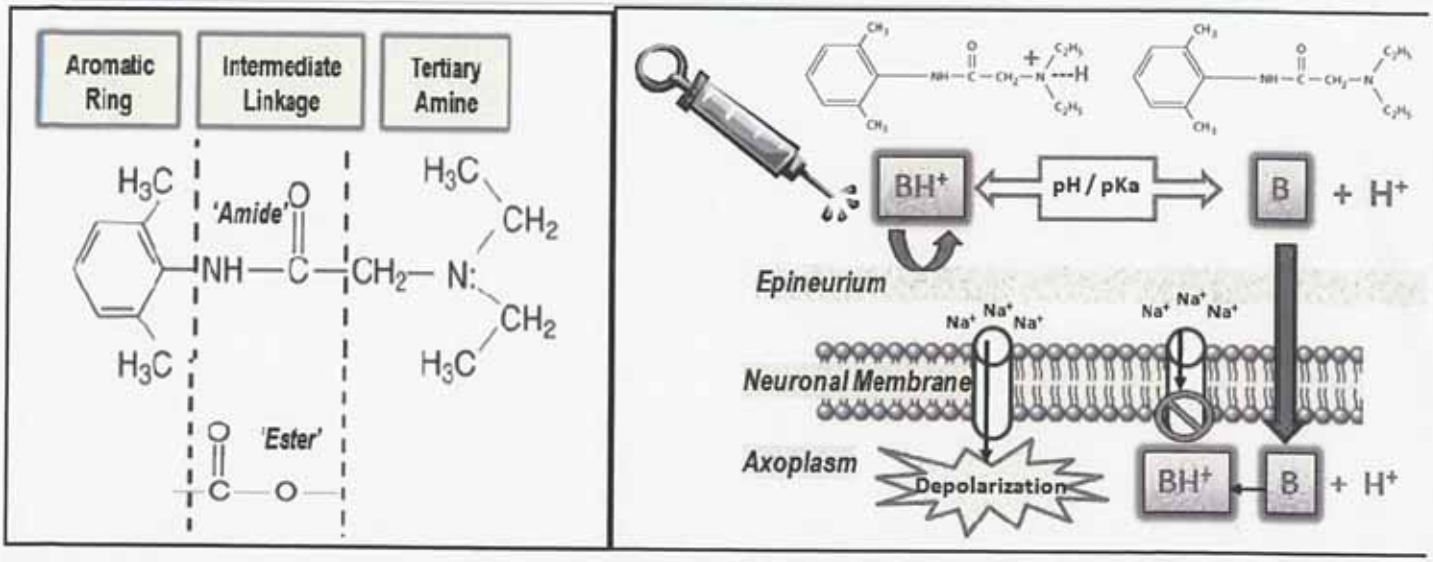
THE NEUROPHYSIOLOGY OF THE BRAIN CENTER

THE LC-CIRCUIT OF LOCAL ANESTHETIC

The Antidote's Resonance frequency, oscillates at the local's LC circuit's Resonance frequency (Tuned Circuit)

GENERAL PROPERTIES OF LOCAL ANESTHETICS



GENERAL

The molecular structure of all local anesthetics consists of 3 components: (a) lipophilic aromatic ring, (b) intermediate ester or amide linkage, and (c) tertiary amine. Each of these components contributes distinct clinical properties to the molecule. (See Figure 1.)

Anesthetic Potency

Local anesthetics vary in their potency, allowing for concentrations that range typically from 0.5 to 4%. This is largely the result of differences in lipid solubility, which enhances diffusion through nerve sheaths and neural membranes. This property is determined by the aromatic ring and its substitutions, along with those added to the tertiary amine. For example, bupivacaine is more lipid soluble and potent than articaine, allowing it to be formulated as a 0.5% concentration (5 mg/mL) rather than a 4% concentration (40 mg/mL).

Time for Onset

. Greater lipid solubility of a drug not only enhances potency but also enables more rapid diffusion through cell membranes. For local anesthetics, this hastens the onset for anesthesia in isolated fibers during in vitro studies, but it must be appreciated that other factors come into play clinically. For example, inherent vasodilating properties may promote systemic absorption before the anesthetic reaches the nerve membrane. High lipid solubility may impede dispersion throughout tissue fluids and also fosters sequestration in neighboring adipose tissues or myelin sheaths. In either case, fewer numbers of molecules reach the neuronal membrane and onset is delayed. Therefore, unlike in vitro studies of isolated fibers, greater lipid solubility generally slows the onset of anesthesia in the clinical setting. Injecting higher concentrations that allow a greater number of molecules to reach the membrane and hasten onset can offset this influence. Although bupivacaine and articaine are both highly lipid soluble, the 4% concentration of articaine provides for a much faster onset.

Local anesthetics are broadly classified into two main groups: Esters and Amides.

LOCAL ANESTHESIA DRUGS

Local anesthesia drugs, commonly called local anesthetics, are medications that numb a specific area of the body, blocking pain signals to the brain without causing loss of consciousness. They are widely used in various medical and dental procedures to minimize discomfort during treatments.

Types of Local Anesthetics:

Local anesthetics are broadly classified into two main groups: Esters and Amides.

Esters: Historically, esters were the first type of local anesthetics developed. Examples include:

Procaine : [Procaine | C13 H20 N2 O2 | CID 4914

A relatively short-acting ester.

Tetracaine: [Tetracaine | C15 H24 N2 O2 | CID 5411 - PubChem

A longer-acting ester, sometimes used for spinal anesthesia.

Chloroprocaine: [Chloroprocaine | C13 H19 Cl N2 O2 | CID 8612 - PubChem

A short-acting ester used for spinal anesthesia.

Cocaine: [Cocaine | C17 H21 N O4 | CID 446220 While an ester, its use is now limited due to its addictive properties and potential for toxicity.

Amides: Amides are the more commonly used local anesthetics today, known for their longer duration of action and lower incidence of allergic reactions compared to esters. Examples include:

Lidocaine: [Lidocaine | C14 H22 N2 O | CID 3676

The most widely used local anesthetic for various procedures, including dental work and minor surgeries.

Mepivacaine: [Mepivacaine | C15 H22 N2 O | CID 4062

A common amide used for dental and regional anesthesia.

Bupivacaine: [Bupivacaine | C18 H28 N2 O | CID 2474 A longer-acting amide, suitable for longer procedures or post-operative pain management.

Ropivacaine: [Ropivacaine | C17 H26 N2 O | CID 175805

Another longer-acting amide, similar to bupivacaine.

Prilocaine: [Prilocaine | C13 H20 N2 O | CID 4906

A common amide used in dentistry and for topical anesthesia.

Mechanism of Action:

Local anesthetics work by blocking nerve impulses, specifically by binding to and inhibiting sodium channels on nerve cell membranes. This prevents the transmission of pain signals from the affected area to the brain, resulting in a numbing effect.

Tetrodotoxin = $C_{11}H_{17}N_3O_8$ } Blockage disrupts Nerve
Saxitoxin = $C_{10}H_{17}N_7O$ } and Muscle-Signalling
GABA-RECEPTOR = $C_4H_9NO_2$ } leading to Paralysis (Anti-Signal)
Sodium-Calcium = $NaCa_2$ (The Inbetween Axon-Links) [14]

General anesthesia

General Anesthesia Drugs induce a reversible state of unconsciousness, allowing for Painless and Pain-free surgical procedures. These drugs are typically administered via intravenous Injection or Inhalation, and often involve a combination of both for Optimal Effect. Common examples include Propofol, Etomidate, Ketamine, and various inhaled anesthetics like Sevoflurane, Isoflurane, and Desflurane.

Propofol : Propofol | C12 H18 O | CID 4943
A commonly used IV anesthetic, known for its rapid onset and offset, making it suitable for both induction and maintenance of anesthesia.

Etomidate : Etomidate | C14 H16 N2 O2 | CID 667484
Another short-acting IV agent, often used for induction, especially in patients with cardiac conditions.

Ketamine : Ketamine | C13 H16 Cl N O | CID 3821 - PubChem
Can be used for both induction and maintenance, and is also known for its analgesic properties.

Thiopental (Sodium Thiopental) : Thiopental | C11 H18 N2 O2 S |3000715
A barbiturate used for induction, but less common now due to the availability of newer agents.

Midazolam : Midazolam | C18 H13 Cl F N3 | CID 4192
A benzodiazepine, often used for sedation and anxiety reduction before and during procedures. Inhaled Agents:

Sevoflurane : Sevoflurane | C4 H3 F7 O | CID 5206
A widely used inhalational Anesthetic, known for its relatively pleasant smell and rapid onset and offset.

Isoflurane : Isoflurane | C3 H2 Cl F5 O | CID 3763
Another common inhalational agent, often used for maintenance of anesthesia.

Desflurane : Desflurane | C3H2F6O | CID 42113
A highly volatile inhalational anesthetic, favored for its rapid changes in depth of anesthesia.

Nitrous Oxide : Nitrous Oxide | N2O | CID 948 - PubChem
Often used in combination with other inhalational agents, particularly for its analgesic properties. Other Important Considerations:

Muscle Relaxants : They are broadly classified into two categories: neuromuscular blockers and spasmolytics. Dicyclomine | C19 H35 N O2 |
Drugs like succinylcholine, vecuronium, and cisatracurium are often used to facilitate intubation and muscle relaxation during surgery.

Analgesics :
Fentanyl | C22H28N2O | CID 3345 - PubChem
Opioids like fentanyl , morphine = Morphine | C17 H19 N O3 | CID 5288826
and hydromorphone = Hydromorphone C17 H20 Cl N O3 | CID 5284570
are frequently used for pain management during and after surgery.

Individualized Approach :The specific combination of drugs used for G-anesthesia is tailored to patient's individual needs, medical history,and the type of procedure being performed.

FOR EYES MUSCLES

Succinylcholine = $C_{14}H_{30}N_2O_4$/6
Vecuronium = $C_{34}H_{57}N_2O_4$ / Bromide = $C_{34}H_{57}BrN_2O_4$
Cisatracurium = $C_{53}H_{72}N_2O_{12}$/14 Besylate = $C_{65}H_{82}N_2O_{18}S_2$

(-)(-)(-)(-) → Many is Short time

Key Considerations:

- **Duration of action:**
  Different local anesthetics have varying durations of action, with some lasting for a short period and others for several hours. (-) Wemax
- **Concentration and dosage:**
  The concentration and dosage of local anesthetics are carefully determined based on the specific procedure, patient weight, and other factors to ensure efficacy and safety.
- **Vasoconstrictors:**
  Vasoconstrictors, such as epinephrine, are often added to local anesthetic solutions to prolong their effect and reduce bleeding at the injection site.
- **Potential side effects:**
  While generally safe, local anesthetics can cause side effects such as allergic reactions, nerve damage, or, in rare cases, systemic toxicity if absorbed into the bloodstream in high concentrations.
- **Topical vs. Injectable:**
  Local anesthetics can be administered topically (e.g., creams, gels, sprays) or through injection (e.g., dental injections, nerve blocks).

Examples of Use:

Local anesthetics are used in a wide range of medical and dental procedures, including:

- Dental fillings and extractions.
- Minor surgical procedures like skin biopsies or stitches.
- Nerve blocks for pain management.
- Epidural anesthesia for childbirth.
- Ophthalmological procedures.
- Wound care.

GLUTAMINE : Glutamine | C5H10N2O3 | CID 5961

is its ability to be converted into α-KG, which helps to maintain the flow of the tricarboxylic acid cycle, generating ATP via the electron carriers NADH = NADH | C21 H29 N7 O14 P2

and FADH = Flavin-Adenine Dinucleotide | C27H33 N9 O15 P2 The highest consumption of glutamine occurs in the cells of the intestines,[7] kidney cells (where it is used

(THC), The primary **Psychoactive component in Cannabis**, tetrahydrocannabinol (THC), **has the chemical formula** C21 H30 O2 . **It is a Terpenophenolic compound, meaning it combines characteristics of terpenoids and phenols. The specific isomer most commonly associated with the effects of marijuana is delta-9-tetrahydrocannabinol (Δ9-THC).**

Cannabidiol (CBD) has the chemical formula C21 H30 O2 and a molecular weight of 314.5 g/mol. It's a terpenophenolic compound with a 21-carbon structure, characterized by two cyclohexene rings. CBD is one of the major non-psychoactive cannabinoids found in cannabis, alongside THC (tetrahydrocannabinol).

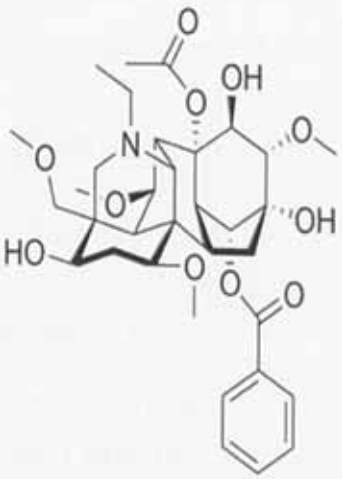
GABA = $C_4H_9NO_2$ → Ligand gated Chanel Complex. Open or Close

CNS = $NaCa_2$ → Node of Ranvier of AXON

Schwan Cell = Vitamin b_1 + Ts = $H_3CN_2NH_2N_5H_{36}OH$

TCR = $C_8H_{18}N_2O_2$ → Reception Protein.

Aconitine



Aconitine is an alkaloid toxin produced by various Plant species belonging to the genus *Aconitum* (family Ranunculaceae), commonly known by the names **wolfsbane** and **monkshood**. Aconitine is notorious for its toxic properties.

Aconitine, a highly toxic alkaloid found in the Aconitum (monkshood) plant, has the chemical formula **C34 H47 N O11** and a molecular weight of 645.74. It is a diterpenoid characterized by a complex cage-like structure with a hexacyclic ring framework (ABCDEF-ring). Aconitine contains three hydroxy groups, three methoxy groups, and one acyloxy group (acetate and benzoate) at specific positions within the molecule

Biosynthesis and total synthesis of related alkaloids

1..Homoponitine = [OCH3]2=[OH]2+ONO2 HNO

2..3-Acetylaponitine = [OCH3]+OH]2+OBz OON Ac OH3COO

3..Guan-fu Base-A = AcON OH HO O Ac

4..Monoponitine = OCH3 + OA3OHOAc OONH3CO

5..Mesaconine = OCH3 + [OH]2 + OONHO H3CO

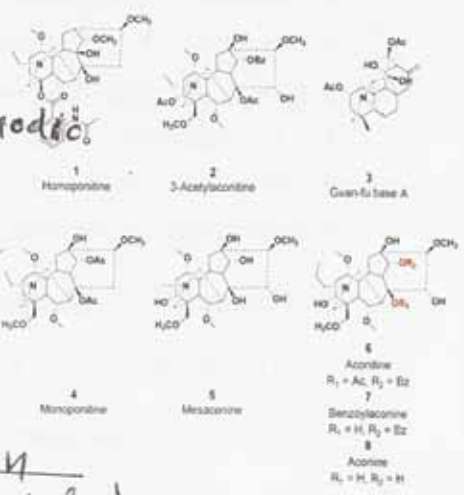
6..Aconitine = OCH3 + [OH]2 + OAc + OBz +OH O2NHO H3CO

7..Benzoylaconine = OCH3 + [OH]2 + OH + OBz +OH O2N HO H3CO

8..Aconine = OCH3 + [OH]2 + OH + OH +OH O2N HO H3CO

9. BellaDonna Alcaloid = $C_{34}H_{42}N_2O_4$
Anticholinergic effects (Parkinson - Antispasmodic, Cramping pains & Spastic colon.

10. Aconidine Alcaloids have Potential Uses as Anti-cancer - Anti Inflammatozy - Analgestec Agents.
ARE Poisons, BUT careful Detoxification and Advance formulations (nanoparticles) can be used for Heart, Liver and Nerves



Drugs and the Brain

Introducing the Human Brain

The human brain is the most complex organ in the body. This three-pound mass of gray and white matter sits at the center of all human activity—you need it to drive a car, to enjoy a meal, to breathe, to create an artistic masterpiece, and to enjoy everyday activities. The brain regulates your body's basic functions, enables you to interpret and respond to everything you experience, and shapes your behavior. In short, *your brain is you*—everything you think and feel, and who you are.

How does the brain work?

The brain is often likened to an incredibly complex and intricate computer. Instead of electrical circuits on the silicon chips that control our electronic devices, the brain consists of billions of cells, called *neurons*, which are organized into circuits and networks. Each neuron acts as a switch controlling the flow of information. If a neuron receives enough signals from other neurons that it is connected to, it fires, sending its own signal on to other neurons in the circuit.

The brain is made up of many parts with interconnected circuits that all work together as a team. Different brain circuits are responsible for coordinating and performing specific functions. Networks of neurons send signals back and forth to each other and among different parts of the brain, the spinal cord, and nerves in the rest of the body (the peripheral nervous system). To send a message, a neuron releases a *neurotransmitter* into the gap (or *synapse)* between it and the next cell. The neurotransmitter crosses the synapse and attaches to receptors on the receiving neuron, like a key into a lock. This causes changes in the receiving cell. Other molecules called *transporters* recycle neurotransmitters (that is, bring them back into the neuron that released them), thereby limiting or shutting off the signal between neurons.

How do drugs work in the brain?

Drugs interfere with the way neurons send, receive, and process signals via neurotransmitters. Some drugs, such as marijuana and heroin, can activate neurons because their chemical structure mimics that of a natural neurotransmitter in the body. This allows the drugs to attach onto and activate the neurons. Although these drugs mimic the brain's own chemicals, they don't activate neurons in the same way as a natural neurotransmitter, and they lead to abnormal messages being sent through the network. Other drugs, such as amphetamine or cocaine, can cause the neurons to release abnormally large amounts of natural neurotransmitters or prevent the normal recycling of these brain chemicals by interfering with transporters. This too amplifies or disrupts the normal communication between neurons.

ANTIDOTE

The Coupling happens when,
The Drug's Resonance frequency oscillates
at the CELL's LC-CIRCUIT Resonance frequency.

How drugs get into cells: Tested and Testable Predictions to ...

Drugs that Block Receptors on or in a Cell and prevent an unwanted Response (in people) or may Prevent a desirable Response causing death (in Pathogens). s.
Agonists bind to Receptors on or in a Cell and stimulate a Response.

Explainer: how do drugs work?

For something that seems so incredible, drug mechanics are wonderfully simple. Whether a drug is prescribed by the doctor, bought over the counter or obtained illegally, we mostly take their mechanism of action for granted and trust they will do what they're supposed to. But how does the ibuprofen pill turn off your headache? And what does the antidepressant do to help balance your brain chemistry?

For something that seems so incredible, drug mechanics are wonderfully simple. It's mostly about receptors and the molecules that activate them.

Receptors.

Receptors are large protein molecules embedded in the cell wall, or membrane. They receive (hence "receptors") chemical information from other molecules – such as drugs, hormones or neurotransmitters – outside the cell.

These outside molecules bind to receptors on the cell, activating the receptor and generating a biochemical or electric signal inside the cell. This signal then makes the cell do certain things such as making us feel pain.

Agonist drugs.

Those molecules that bind to specific receptors and cause a process in the cell to become more active are called agonists. An agonist is something that causes a specific physiological response in the cell. They can be natural or artificial.

For instance, endorphins are natural agonists of opioid receptors. But morphine – or heroin that turns into morphine in the body – is an artificial agonist of the main opioid receptor.

An artificial agonist is so structurally similar to a receptor's natural agonist that it can have the same effect on the receptor. Many drugs are made to mimic natural agonists so they can bind to their receptors and elicit the same – or much stronger – reaction.

Simply put, an agonist is like the key that fits in the lock (the receptor) and turns it to open the door (or send a biochemical or electrical signal to exert an effect). The natural agonist is the master key but it is possible to design other keys (agonist drugs) that do the same job.

Morphine, for instance, wasn't designed by the body but can be found naturally in opium poppies. By luck it mimics the shape of the natural opioid agonists, the endorphins, that are natural pain relievers responsible for the "endorphin high".

Specific effects such as pain relief or euphoria happen because opioid receptors are only present in some parts of the brain and body that affect those functions.

The main active ingredient in cannabis, THC, is an agonist of the cannabinoid receptor, and hallucinogenic drug LSD is a synthetic molecule mimicking the agonist actions of the neurotransmitter serotonin at one of its many receptors – the 5HT2A receptor.

Antagonist drugs $C_{10}H_{12}N_2O$ $C_{10}H_{12}N_2O$

An antagonist is a drug designed to directly oppose the actions of an agonist.

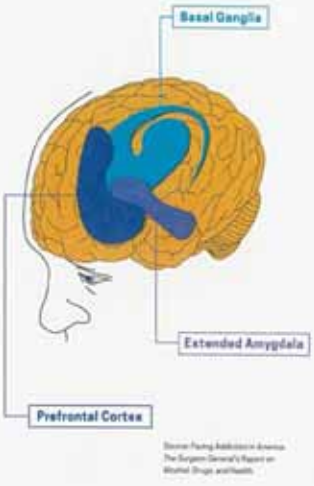
The Resonance of Antidotes and Local or General Neurotransmitting System allows Drugs to couple with Receptors and Neurotransmitters.

Again, using the lock and key analogy, an antagonist is like a key that fits nicely into the lock but doesn't have the right shape to turn the lock. When this key (antagonist) is inserted in the lock, the proper key (agonist) can't go into the same lock.
So the actions of the agonist are blocked by the presence of the antagonist in the receptor molecule.
Again, let's think of morphine as an agonist for the opioid receptor. If someone is experiencing a potentially lethal morphine overdose, the opioid receptor antagonist naloxone can reverse the effects. $C_{19}H_{21}NO_4$
This is because naloxone (marketed as Narcan) quickly occupies all the opioid receptors in the body and prevents morphine from binding to and activating them.
Morphine bounces in and out of the receptor in seconds. When it's not bound to the receptor, the antagonist can get in and block it. Because the receptor can't be activated once an antagonist is occupying the receptor, there is no reaction.
The effects of Narcan can be dramatic. Even if the overdose victim is unconscious or near death, they can become fully conscious and alert within seconds of injection.
Membrane transport inhibitors $C_{19}H_{21}NO_4$-5
Membrane transporters are large proteins embedded in a cell's membrane that shuttle smaller molecules – such as neurotransmitters – from outside of the cell that releases them, back to the inside. Some drugs act to inhibit their action.
Selective serotonin reuptake inhibitors (SSRIs) – such as the antidepressant fluoxetine (Prozac) – work like this. $C_{17}H_{18}F_3NO$
Serotonin is a brain neurotransmitter that regulates mood, sleep and other functions such as body temperature. It's released from nerve terminals, binding to serotonin receptors on nearby cells in the brain.
For the process to work smoothly, the brain must quickly turn off the signals coming from the serotonin soon after the chemicals are released from the terminals. Otherwise moment-to-moment control of brain and body function would be impossible.
The brain does so with the help of serotonin transporters in the nerve terminal membrane. Like a vacuum cleaner, the transporters scoop serotonin molecules that haven't bound to receptors and transport them back to the inside of the terminal for later use. SSRI drugs work by getting stuck inside the vacuum hose so unbound serotonin molecules can't be transported back into the terminal.
Because more serotonin molecules are then hanging around receptors for longer, they continue to stimulate them.
We can crudely say the extra serotonin moderately turns up the volume of the signal to enhance positive mood. But the actual way this has an effect on depression and anxiety is far more complicated. $C_{400}H_{620}N_{100}O_{120}P_5S$
Around 40 per cent of all medicinal drugs target just one superfamily of receptors – the G-protein coupled receptors. There are variations on these drug mechanisms, including partial agonists and ones that act like antagonists but slightly differently. Overall though, a lot of drugs actions fall into the categories described above.
This article by Professor Mac Christie was originally published in The Conversation. He is a Professor of Pharmacology and Associate Dean (Research), Sydney Medical School at the University of Sydney.

CONCLUSION

THE ANTIDOTES, ENTER TO THE LOCAL OR TO THE BRAIN <neurus-cell-System> THROUGH THE BLOOD. THE ANTIDOTE'S SIGNALLING mimics that of LOCAL OR OF THE BRAIN NEUROTRANSMITTERS, and thus, ALLOWS TO ITS ATTACH ONTO AND ACTIVATE THE <neurus-Cell-System>

What parts of the brain are affected by drug use?



Drugs can alter important brain areas that are necessary for life-sustaining functions and can drive the compulsive drug use that marks addiction. Brain areas affected by drug use include :

- *The basal ganglia,* which play an important role in positive forms of motivation, including the pleasurable effects of healthy activities like eating, socializing, and sex, and are also involved in the formation of habits and routines. These areas form a key node of what is sometimes called the brain's "reward circuit." Drugs over-activate this circuit, producing the euphoria of the drug high. But with repeated exposure, the circuit adapts to the presence of the drug, diminishing its sensitivity and making it hard to feel pleasure from anything besides the drug.
- *The extended amygdala* plays a role in stressful feelings like anxiety, irritability, and unease, which characterize withdrawal after the drug high fades and thus motivates the person to seek the drug again. This circuit becomes increasingly sensitive with increased drug use. Over time, a person with substance use disorder uses drugs to get temporary relief from this discomfort rather than to get high.
- *The prefrontal cortex* powers the ability to think, plan, solve problems, make decisions, and exert self-control over impulses. This is also the last part of the brain to mature, making teens most vulnerable. Shifting balance between this circuit and the circuits of the basal ganglia and extended amygdala make a person with a substance use disorder seek the drug compulsively with reduced impulse control. Some drugs like opioids also disrupt other parts of the brain, such as the brain stem, which controls basic functions critical to life, including heart rate, breathing, and sleeping. This interference explains why overdoses can cause depressed breathing and death.

How do drugs produce pleasure?

Simple activities in everyday life can produce small bursts of neurotransmitters in the brain bringing pleasurable feelings. Drugs can hijack that process.

Pleasure or euphoria—the high from drugs—is still poorly understood, but probably involves surges of chemical signaling compounds including the body's natural opioids (endorphins) and other neurotransmitters in parts of the basal ganglia (the reward circuit). When some drugs are taken, they can cause surges of these neurotransmitters much greater than the smaller bursts naturally produced in association with healthy rewards like eating, hearing or playing music, creative pursuits, or social interaction.

Euphoria from Drugs happens when couples, The Drug's Resonance frequency - and oscillates at the Brain-Part LC-CIRCUIT = The Reward. Circuit. Resonance frequency.

It was once thought that surges of the neurotransmitter *dopamine* produced by drugs directly caused the euphoria, but scientists now think dopamine has more to do with getting us to repeat pleasurable activities (reinforcement) than with producing pleasure directly.

How does dopamine reinforce drug use?

The feeling of pleasure is how a healthy brain identifies and reinforces beneficial behaviors, such as eating, socializing, and sex. Our brains are wired to increase the odds that we will repeat pleasurable activities. The neurotransmitter dopamine is central to this. Whenever the reward circuit is activated by a healthy, pleasurable experience, a burst of dopamine signals that something important is happening that needs to be remembered. This dopamine signal causes changes in neural connectivity that make it easier to repeat the activity again and again without thinking about it, leading to the formation of habits. Just as drugs produce intense euphoria, they also produce much larger surges of dopamine, powerfully reinforcing the connection between consumption of the drug, the resulting pleasure, and all the external cues linked to the experience. Large surges of dopamine "teach" the brain to seek drugs at the expense of other, healthier goals and activities.

Cues in a person's daily routine or environment that have become linked with drug use because of changes to the reward circuit can trigger uncontrollable cravings whenever the person is exposed to these cues, even if the drug itself is not available. This learned "reflex" can last a long time, even in people who haven't used drugs in many years. For example, people who have been drug free for a decade can experience cravings when returning to an old neighborhood or house where they used drugs. Like riding a bike, the brain remembers.

Why are drugs more addictive than natural rewards?

For the brain, the difference between normal rewards and drug rewards can be likened to the difference between someone whispering into your ear and someone shouting into a microphone. Just as we turn down the volume on a radio that is too loud, the brain of someone who misuses drugs adjusts by producing fewer neurotransmitters in the reward circuit, or by reducing the number of receptors that can receive signals. As a result, the person's ability to experience pleasure from naturally rewarding (i.e., reinforcing) activities is also reduced. This is why a person who misuses drugs eventually feels flat, without motivation, lifeless, and/or depressed, and is unable to enjoy things that were previously pleasurable. Now, the person needs to keep taking drugs to experience even a normal level of reward—which only makes the problem worse, like a vicious cycle. Also, the person will often need to take larger amounts of the drug to produce the familiar high—an effect known as *tolerance.*

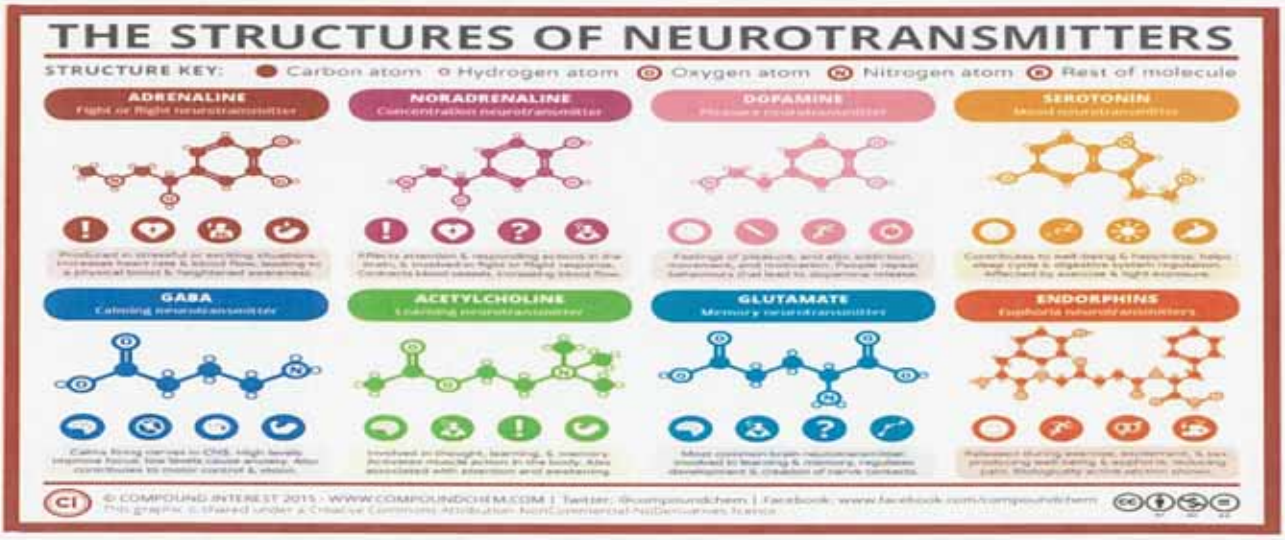
Long-term drug use impairs brain functioning.

Extended Amygdala

The extended Amygdala, a Brain region involved in stress and emotional responses, is characterized by a complex interplay of neurotransmitters and receptors. Key components include the bed nucleus of the stria terminalis (BNST), the central nucleus of the Amygdala (CeA), and the nucleus Accumbens shell.These regions are rich in various Neurotransmitters like GABA= **[C4H9NO2] Glutamate= [** C5 H7 N O4 **],** **Dopamine =** [C8 H11 N O2] , **and Serotonin** = [C10 H12 N2 O], **as well as** Neuro-peptides = [H2 N–ONO-N H] such as corticotropin-releasing factorCRFand substance

Prefrontal cortex

The Prefrontal cortex (PFC) doesn't have a chemical structure in the same way that molecules do. Instead, it's a region of the Brain composed of neurons,glial cells&various chemical messengers (neurotransmitters) that allow it to function. The PFC's structure & the interplay of these chemicals determine its role in higher-level cognitive functions.



1 = Adrenaline = [C9 H13 N O3] → Pleasure – Drug .

2 = Nor-Adrenaline = [C8 H11 N O3]

3 = Dopamine = [C8 H11 N O2] → Pleasure – Drug .

4 = Seratonine = [C10 H12 N2 O] → Pleasure – Drug .

6 = Acetylcholine = **[C7 H16 N O 2]**

7 = Glutamate = **[C77 H120 N18 O26 S]**

8 = A-Endorphin = **[C77 H120 N18 O26 S]** → Agonist of Opioid

9 = B-Endorphin = **[C77 H120 N18 O26 S]**

10= Amphetamine = [C9 H13 N] → Pleasure – Drug .

11= LSD = [C20 H25 N3 O] → Pleasure – Drug .

12= Psilocybin = [C12 H12 N2 O4 P] → Pleasure – Drug .

13= GHB-***Depressed*** = [C4 H8 O3] → Depressed – Drug .

14= ***Hydroxybutaneate*** = [C4 H7 O3] → Depressed – Drug

15 = Morphine = $[C_{17}H_{19}NO_3]$ → Artificial Agonist-Opioid

16 = Heroin = $[C_{21}H_{23}NO_5]$ → Artificial Agonist-Opioid

Chemotherapy:

Breast cancer treatments utilize various drugs to target cancer cells and inhibit their growth. Chemotherapy uses cytotoxic drugs to kill cancer cells, while targeted therapy focuses on specific proteins on cancer cells to hinder their survival and spread. Hormone therapy blocks hormones that promote cancer growth, and immunotherapy uses the body's immune system to fight cancer.

- **Mechanism:** $C_{27}H_{29}NO_{11}$ $C_7H_{15}Cl_2N_2O_2P$

Chemotherapy drugs, like epirubicin and cyclophosphamide, are cytotoxic, meaning they kill rapidly dividing cells. **They disrupt cell division and** DNA replication, ultimately leading tocell death.

- **Application:**

Chemotherapy is often used to shrink tumors before surgery, eliminate remaining cancer cells after surgery, or treat advanced breast cancer.

- **Types:**

Various chemotherapy drugs exist, each targeting cancer cells in different ways. For example, some damage DNA, while others interfere with cell division or metabolism.

- **Side Effects:**

Due to their effect on rapidly dividing cells, chemotherapy drugs can also affect healthy cells, leading to side effects like hair loss, nausea, and fatigue.

Targeted Therapy:

- **Mechanism:** $C_{29}H_{26}ClFN_4O_4S$

Targeted therapies focus on specific proteins or pathways involved in cancer cell growth and survival. For example, drugs like lapatinib block HER2 receptors, which are overexpressed in some breast cancers, hindering cell growth. Glycoprotein $C_{28}H_{47}N_5O_{18}$

- **Application:**

Targeted therapies are often used in conjunction with chemotherapy or hormone therapy to enhance treatment effectiveness.

- **Types:** $C_{18}H_{29}NO$

Targeted therapies include drugs that block hormone receptors (like tamoxifen and aromatase inhibitors), HER2 inhibitors (like trastuzumab), and drugs that target other specific proteins involved in cancer cell growth. $C_{6470}H_{10012}N_{1726}O_{2013}S_{42}$

Hormone Therapy:

- **Mechanism:**

Hormone therapy targets hormone receptors on breast cancer cells, preventing hormones like estrogen from promoting cancer cell growth.

- **Application:** $C_{18}H_{24}O_2$

Hormone therapy is typically used for estrogen receptor-positive breast cancers, which rely on estrogen for growth.

- **Types:** $C_{17}H_{19}N_5$

Common hormone therapies include tamoxifen, aromatase inhibitors (like anastrozole), and fulvestrant. **Immunotherapy:**

- **Mechanism:** $C_{32}H_{47}F_5O_3S$

Immunotherapy drugs stimulate the body's own immune system to recognize and attack cancer cells.

- **Application:**

Immunotherapy is a newer approach to breast cancer treatment, particularly for advanced or metastatic breast cancer.

All Drugs for Chemotherapy can be Tested. for their coupling to the Local or General. Neurotransmitting System, through their LC-CIRCUITS for Resoning.

LOCAL ANESTHESIA DRUGS

Local anesthesia drugs, commonly called local anesthetics, are medications that numb a specific area of the body, blocking pain signals to the brain without causing loss of consciousness. They are widely used in various medical and dental procedures to minimize discomfort during treatments.

Types of Local Anesthetics:

Local anesthetics are broadly classified into two main groups: Esters and Amides.

Esters: Historically, esters were the first type of local anesthetics developed. Examples include:

Procaine : [Procaine | C13 H20 N2 O2 | CID 4914

A relatively short-acting ester.

Tetracaine: [Tetracaine | C15 H24 N2 O2 | CID 5411 - PubChem

A longer-acting ester, sometimes used for spinal anesthesia.

Chloroprocaine: [Chloroprocaine | C13 H19 Cl N2 O2 | CID 8612 - PubChem

A short-acting ester used for spinal anesthesia.

Cocaine: [Cocaine | C17 H21 N O4 | CID 446220 While an ester, its use is now limited due to its addictive properties and potential for toxicity.

Amides: Amides are the more commonly used local anesthetics today, known for their longer duration of action and lower incidence of allergic reactions compared to esters. Examples include:

Lidocaine: [Lidocaine | C14 H22 N2 O | CID 3676

The most widely used local anesthetic for various procedures, including dental work and minor surgeries.

Mepivacaine: [Mepivacaine | C15 H22 N2 O | CID 4062

A common amide used for dental and regional anesthesia.

Bupivacaine: [Bupivacaine | C18 H28 N2 O | CID 2474 A longer-acting amide, suitable for longer procedures or post-operative pain management.

Ropivacaine: [Ropivacaine | C17 H26 N2 O | CID 175805

Another longer-acting amide, similar to bupivacaine.

Prilocaine: [Prilocaine | C13 H20 N2 O | CID 4906

A common amide used in dentistry and for topical anesthesia.

Mechanism of Action:

Local anesthetics work by blocking nerve impulses, specifically by binding to and inhibiting sodium channels on nerve cell membranes. This prevents the transmission of pain signals from the affected area to the brain, resulting in a numbing effect.

- Tetrodotoxin = $C_{11}H_{17}N_3O_8$ } Blockage disrupts Nerve
- Saxitoxin = $C_{10}H_{17}N_7O$ } and Muscle-Signalling
- GABA-RECEPTOR = $C_4H_9NO_2$ } leading to Paralysis (Anti-Signal)
- Sodium-Calcium = $NaCa_2$ (The Inbetween Axon-Links)

General anesthesia

General Anesthesia Drugs induce a reversible state of unconsciousness, allowing for Painless and Pain-free surgical procedures. These drugs are typically administered via intravenous Injection or Inhalation, and often involve a combination of both for Optimal Effect. Common examples include Propofol, Etomidate, Ketamine, and various inhaled anesthetics like Sevoflurane, Isoflurane, and Desflurane.

Propofol : Propofol | C12 H18 O | CID 4943
A commonly used IV anesthetic, known for its rapid onset and offset, making it suitable for both induction and maintenance of anesthesia.

Etomidate : Etomidate | C14 H16 N2 O2 | CID 667484
Another short-acting IV agent, often used for induction, especially in patients with cardiac conditions.

Ketamine : Ketamine | C13 H16 Cl N O | CID 3821 - PubChem
Can be used for both induction and maintenance, and is also known for its analgesic properties.

Thiopental (Sodium Thiopental) : Thiopental | C11 H18 N2 O2 S |3000715
A barbiturate used for induction, but less common now due to the availability of newer agents.

Midazolam : Midazolam | C18 H13 Cl F N3 | CID 4192
A benzodiazepine, often used for sedation and anxiety reduction before and during procedures. Inhaled Agents:

Sevoflurane : Sevoflurane | C4 H3 F7 O | CID 5206
A widely used inhalational Anesthetic, known for its relatively pleasant smell and rapid onset and offset.

Isoflurane : Isoflurane | C3 H2 Cl F5 O | CID 3763
Another common inhalational agent, often used for maintenance of anesthesia.

Desflurane : Desflurane | C3H2F6O | CID 42113
A highly volatile inhalational anesthetic, favored for its rapid changes in depth of anesthesia.

Nitrous Oxide : Nitrous Oxide | N2O | CID 948 - PubChem
Often used in combination with other inhalational agents, particularly for its analgesic properties. Other Important Considerations:

Muscle Relaxants : They are broadly classified into two categories: neuromuscular blockers and spasmolytics. Dicyclomine | C19 H35 N O2 |
Drugs like succinylcholine, vecuronium, and cisatracurium are often used to facilitate intubation and muscle relaxation during surgery.

Analgesics :
Fentanyl | C22H28N2O | CID 3345 - PubChem
Opioids like fentanyl , morphine = Morphine | C17 H19 N O3 | CID 5288826
and hydromorphone = Hydromorphone C17 H20 Cl N O3] CID 5284570
are frequently used for pain management during and after surgery.

Individualized Approach :The specific combination of drugs used for G-anesthesia is tailored to patient's individual needs, medical history,and the type of procedure being performed.

FOR EYES MUSCLES
Succinylcholine = $C_{14}H_{30}N_2O_{4/6}$
Vecuronium = $C_{34}H_{57}N_2O_4$ / Bromide = $C_{34}H_{57}BrN_2O_4$
Cisatracurium = $C_{53}H_{72}N_2O_{12/14}$ Besylate = $C_{65}H_{82}N_2O_{18}S_2$

(-)(-)(-)(-) → Many is Short time

Key Considerations:

- **Duration of action:**
  Different local anesthetics have varying durations of action, with some lasting for a short period and others for several hours. (-) Wamax
- **Concentration and dosage:**
  The concentration and dosage of local anesthetics are carefully determined based on the specific procedure, patient weight, and other factors to ensure efficacy and safety.
- **Vasoconstrictors:**
  Vasoconstrictors, such as epinephrine, are often added to local anesthetic solutions to prolong their effect and reduce bleeding at the injection site.
- **Potential side effects:**
  While generally safe, local anesthetics can cause side effects such as allergic reactions, nerve damage, or, in rare cases, systemic toxicity if absorbed into the bloodstream in high concentrations.
- **Topical vs. Injectable:**
  Local anesthetics can be administered topically (e.g., creams, gels, sprays) or through injection (e.g., dental injections, nerve blocks).

Examples of Use:

Local anesthetics are used in a wide range of medical and dental procedures, including:

- Dental fillings and extractions.
- Minor surgical procedures like skin biopsies or stitches.
- Nerve blocks for pain management.
- Epidural anesthesia for childbirth.
- Ophthalmological procedures.
- Wound care.

GLUTAMINE : Glutamine | C5H10N2O3 | CID 5961

is its ability to be converted into α-KG, which helps to maintain the flow of the tricarboxylic acid cycle, generating ATP via the electron carriers NADH = NADH | C21 H29 N7 O14 P2

and FADH = Flavin-Adenine Dinucleotide | C27H33 N9 O15 P2 The highest consumption of glutamine occurs in the cells of the intestines,[7] kidney cells (where it is used

(THC), The primary **Psychoactive component in Cannabis**, tetrahydrocannabinol (THC), **has the chemical formula C21 H30 O2 . It is a Terpenophenolic compound, meaning it combines characteristics of terpenoids and phenols. The specific isomer most commonly associated with the effects of marijuana is delta-9-tetrahydrocannabinol (Δ9-THC).**

Cannabidiol (CBD) has the chemical formula C21 H30 O2 and a molecular weight of 314.5 g/mol. It's a terpenophenolic compound with a 21-carbon structure, characterized by two cyclohexene rings. CBD is one of the major non-psychoactive cannabinoids found in cannabis, alongside THC (tetrahydrocannabinol).

GABA = $C_4H_9NO_2$ → Ligand gated Channel Complex. Open or Close

CNS = $NaCaZ$ → Node of Ranvier of AXON

Sahwann Cell = Vitamin b_1 + Ts = $H_3CN_2NH_2N_5H_{36}OH$

TCR = $C_8H_{18}N_2O_2$ → Reception Protein.

	[AN] = 55.[N2 Pt Cl2 H6]			= **14,84** V → MF = **1,56.10⁻⁶** T
MODULATED & G-ANESTHESIA	KETAMINE = ANTIDOTE			[M]+[AN] = [CNS] = **1143,4** V
	[AN] = 27.[C13 Hl6 Cl N O]			=**188,05** V → MF =**1,91.10⁻⁶** T
MODULATED & L-ANESTHESIA	KETAMINE = COCAINEE			[M]+[AN] = [CNS] = **1142,8** V

Some Explanations from , Article [111] , Regarding the Atoms-Bonding .

1... The Resonance of 2 frequencies A , B occurs , when their Natural-frequencies coincide , **i.e.** it is valid A = B . In the Same Voltages and Magnetic -Field .

2... The two frequencies A , B , **are coupled** , **when** a Third frequency C is added so that A , B , are in Resonance , **i.e.** it is valid A + C = B + C. That is ,

3... **WHEN** [A] **is** an carrier wave , [B] **is** the modulating wave , [M] = [A] + [B] **is** the modulated wave , [DM] **is** the demodulated wave , [AN] **is** the Antidote , [LNS] **is** the Local Nervous System , [CNS] **is** the Central Nervous System , **THEN** for the coupled frequencies it is valid → [M] + [AN] = [LNS] & also [M] + [AN] = [CNS] ← **That is , The Antidotes** , [AN] are those frequencies as the above [C] that are added **so that** [A] , [B] **are in Resonance with them** to Voltage & M-Field

4...**The Uncoupled values are inside of the Coupled Natural frequencies by small** Amounts .The multitude of numbers of the uncoupled signaling Systems are placed to the **Sidebands** as this is the in Program →**Athwart Energy Vibration Spectrum.**

5... Placing⇒ [M] = [A] + [B] → The Modulated Wave .
[AN] = [C] → The Antidote ,
[M] + [AN] = [LNS] → **IS in Resonance to Local Nervous System ,**
[M] + [AN] = [CNS] → **IS in Resonance to Central-Nervous System**

THE TRANSPORTATION OF DRUGS TO THE CANCEROUS OR-NOT CELLS

Conclusion-1 :

TATP – Explosive enters the Cell through ,

1...The Ascending motion of the Carriers Wave ,

2... The Jumping on the Cells neurotransmitters , and their coupled from the miming to their common Modulated Wave . Coupling Resonance frequency tuning $[W_{TATP-F}] . \sqrt{L.C} = 1$

3...The Combination of the Antidotes Resonance-frequency , to that of the Natural frequency of Nucleus tuning circuit ($[W_{TATP-F}].\sqrt{L.C}$) &TATP- tuning circuit ($[W_{TATP-F}].\sqrt{L.C}$)

Conclusion-2 :

The Frequency coupling describes **the Interaction** between two or more oscillating frequencies, *Carrier–Modulating-Antidotes Waves* , where the behavior of one frequency is influenced by the Presence and characteristics of the other (***The ProgramsAthwart Energy Vibrating Spectrum***).This can manifest in various ways, including frequency mixing (creating new frequencies and Compounds = ***The Modulating Wave***) , Resonance (amplification when frequencies align) , or more complex interactions like Cross-frequency Coupling = *The Side Band* (CFC) in Neural Systems .

This interaction plays a role in neural computation, communication , and learning, Potentially linking as this in Local and in Global Brain activity.

The Cross-Frequency Coupling (CFC) ≡ **From** ***Program`s Athwart Energy Vibrating Spectrum*** = CFC is a Phenomenon observed in Neural- Systems , where the Phase , φ , of a Low-frequency oscillation influences the Amplitude of a Higher-frequency oscillation . This interaction Play a role in Neural computation , communication , and learning , Potentially linking Local and Global Brain activity . For Signals issues the Voltage-current relation $V_{LOW} \cdot i_{LOW} \cdot \cos\varphi = V_{HIGH} \cdot i_{HIGH} \cdot \cos\varphi$.

The Program`s General Applications :

1... IN Radio and Telecommunications :

The Frequency mixing [***The Prober Modulating on the Carrier Wav***] is essential for radio transmission and Reception .

2... IN Neural Networks :

[CFC] is to understand how the different Brain regions communicate and process Information , [***The Demodulation of an Modulated - Wave***].

3... CONTROLLING The effectiveness of Drugs :

Markos Program is based on the Analysis of the Process and Antidote Action as ,

→ The **Carrier – Modulating – Modulated – Demodulation Waves Process** ←

[*The Final Modulated – Compound* + ***Antidote`s Frequency*** **Resonates** , *to that Of the* (*Normal* ***or*** *Abnormal*) (*Local* ***or*** *Central*) , *Cell`s Nervous System*] . All Actions between the Drugs &those of the Cells happen between their own **Resonant LC-circuits.**

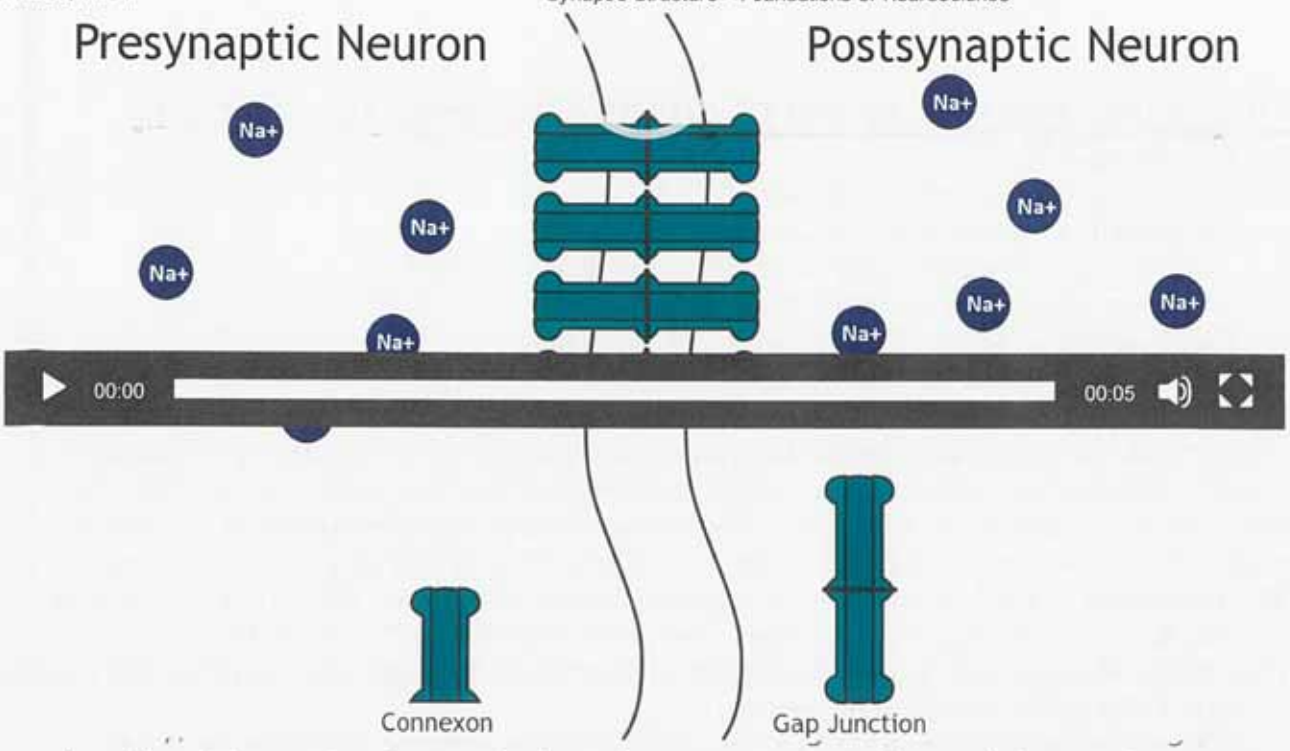
4... IN The Optical and microwave Resonators :

Coupled-mode theory analyzes the behavior of these Systems , and is in

[**The** ***Demodulating from the Athwart Energy Vibrating Spectrum***]

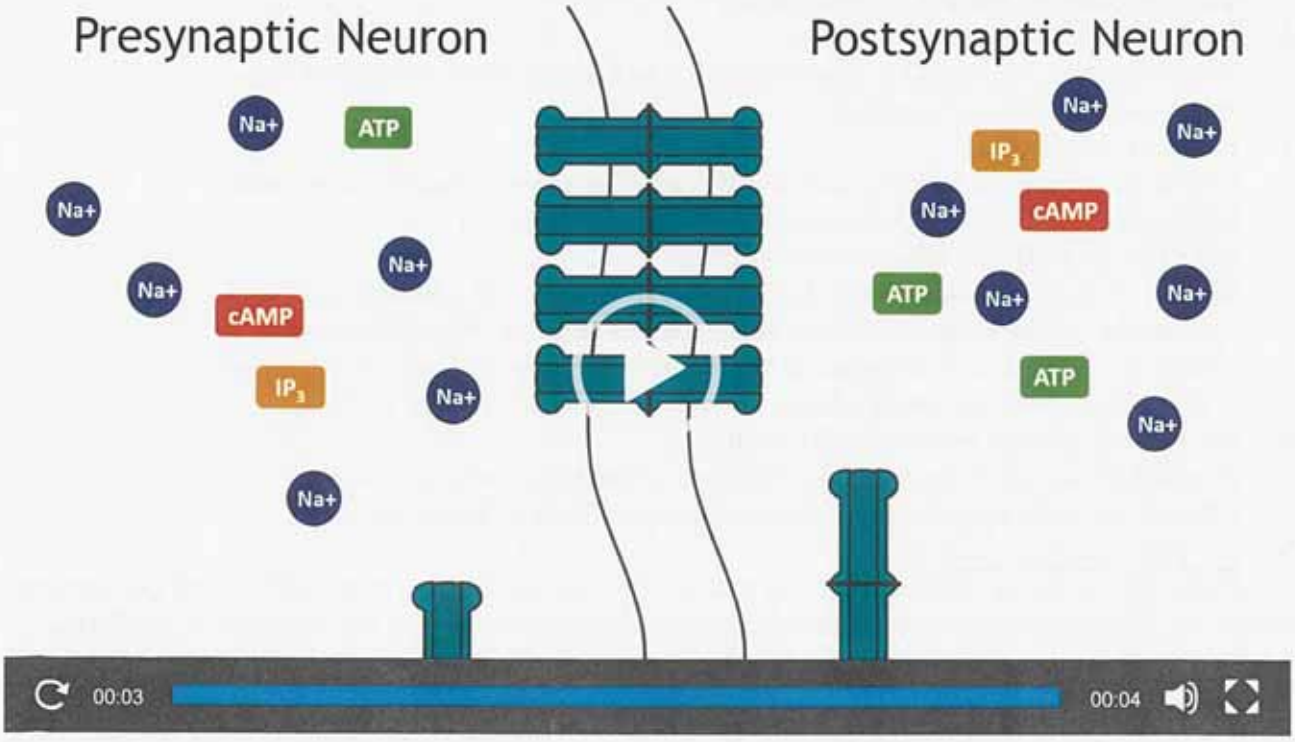
5... IN The Grid-tied converters :

Frequency coupling effects can occur in these Systems impacting their stability and performance . In essence, frequency-coupling is a broad concept which describes how the behavior of oscillating frequencies [***Markos-Programming the Atoms and their Compounds Bonding***] can be influenced by their interaction with each other, leading to various Phenomena and Applications across diverse fields . On the Cell`s membrane Lipid bilayer , in order to generate a sufficient Voltage for the 1-Volt three-Phase grid , there must be at least a Direct Voltage of $V_{DC-min} = 1V . \sqrt{2} = 1{,}4142$ V at the Input of the Head-Invertor [111] . All Interactions of Coupling is an Electrical-Resonator (a tuned circuit) storing Energy , and oscillating at the circuit`s Resonant - frequency . In the case of Drugs , The storing Energy of , Antidotes LC-circuit ⇒ Drug , flows to the CELL`s LC-circuit .....



gap junctions. These signaling molecules play an important role in cellular mechanisms, which we will see in a later chapter.

LC-circuit



Animation 8.3. Gap junctions are large enough to allow the flow of small cellular molecules like ATP or second messengers. IP_3 = $[C_6H_{15}O_{15}P_3]$

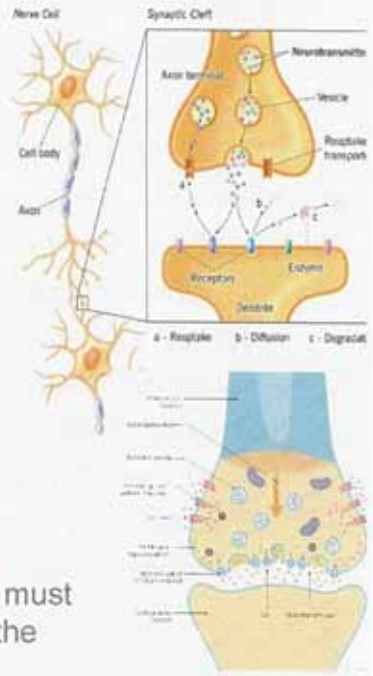
Chemical



What are neurotransmitters ? The Synapse

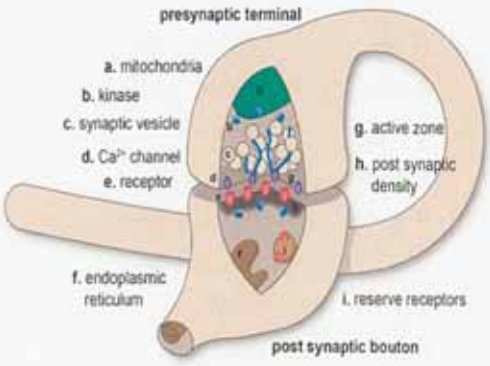
Neurotransmitters are chemical messengers that your body can't function without. Their job is to carry chemical Signals ("messages) from one neuron (nerve cell) to the next target cell. The next target cell can be another nerve cell, a muscle cell or a gland.
Your body has a vast network of nerves (your nervous system) that send and receive electrical Signals from nerve cells and their target cells all over your body. Your nervous System controls everything from your mind to your muscles, as well as organ functions. In other words, nerves are involved in everything you do, **think and feel**. Your nerve cells send and receive information from all body sources. This constant feedback is essential to your body's optimal function.

What happens to neurotransmitters after they deliver their message? After neurotransmitters deliver their message, the molecules must be cleared from the synaptic cleft (the space between the nerve cell and the next target cell). They do this in one of three ways.

Neurotransmitters:

- Fade away (a process called diffusion).
- Are reabsorbed and reused by the nerve cell that released it (a process
- called reuptake).
- Are broken down by enzymes within the synapse so it can't be recognized
- or bind to the receptor cell (a process called degradation).

The Voltage Gate = Between Postsynaptic Neuron & Presynaptic Neuron Chemical Synapses rely on Neurotransmitters to bridge the synaptic Cleft, [The Electromagnetic LC *circuit* of the Antidotes Actions] , facilitating slower, unidirectional Signalling .



Integration of Synaptic inputs

Main article: Summation (neurophysiology)
In general, if an excitatory synapse is strong enough, Then An Action - Potential in the **Presynaptic- neuron** will trigger an Action - Potential in the **Postsynaptic cell**. In many cases the excitatory Postsynaptic Potential (EPSP) will not reach the threshold for eliciting an action potential. When action Potentials from multiple Presynaptic Neurons fire simultaneously, or if a single Presynaptic Neuron fires at a high enough frequency , the EPSPs can overlap and summate. If enough EPSPs overlap , the summated EPSP can reach the threshold for initiating an action potential. This process is known as summation, and can serve as a high pass filter for neurons.**On the other hand, a Presynaptic Neuron releasing an Inhibitory Neurotransmitter, such as GABA , can cause an inhibitory Postsynaptic- Potential (IPSP) in the Postsynaptic Neuron, bringing the membrane Potential farther away from the threshold, decreasing its excitability and making it more difficult for the neuron to initiate an action Potential. If an IPSP overlaps with an EPSP, the IPSP can in many cases prevent the neuron**

from firing an action Potential. In this way, the output of a neuron may depend on the input of many different neurons, each of which may have a different degree of influence, depending on the strength and type of synapse with that neuron. John Carew Eccles performed some of the important early experiments on synaptic integration, for which he received the Nobel Prize for Physiology or Medicine in 1963.and complexity in communication compared to electrical synapses.

THE CHEMICAL ELEMENTS IN SYNAPSES . Na3

Adenosine Triphosphate | C10 H16 N5 O13 P3 | CID 5957

ATP is an adenosine 5'-phosphate in which the 5'-phosphate is a triphosphate group. It is involved in the transportation of chemical energy during metabolic ...

Adenosine cyclic phosphate | C10 H12 N5 O6 P | CID 6076

Molecular Formula. C10H12N5O6P ; Synonyms. Cyclic AMP; cAMP; 60-92-4; Adenosine 3',5'-cyclic monophosphate; 3',5'-cyclic AMP ; Molecular Weight. 329.21 g/mol.

Inositol trisphosphate = $C_6 H_{15} O_{15} P_3$.

Its empirical formula is $C_6H_{15}O_{15}P_3$. It is composed of an inositol ring with three phosphate groups bound at the 1, 4, and 5 carbon positions, and three ...

3...SYNAPSES ANTIDOTE 59.[c.AMP] = 59.[C10 H12 N5 O6 P] occupies the **Resonance** Circular Frequency W [c.AMP] = 47,151.10^{15} Hz ≡ W [AN-CIS] .

4...SYNAPSES ANTIDOTE 137.[In.TRI] = 137.[C6 H15 O15 P3] occupies the **Resonance** Circular Frequency W [c.AMP] = 47,151.10^{15} Hz ≡ W [AN-CIS] .

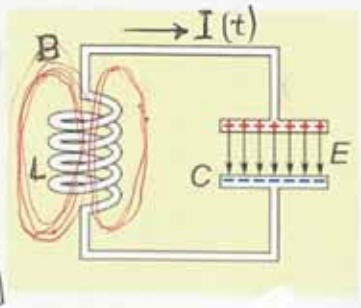
5...SYNAPSES ANTIDOTE 160.[In.TRI] = 160.[C6 H15 O15 P3] occupies the **Resonance** Circular Frequency W [c.AMP] = 50,792.10^{15} Hz >> W [AN-CIS] .

6...SYNAPSES ANTIDOTE 160.[In.TRI] + 250.N = 160.[C6 H15 O15 P3] + 250.N occupies the **Resonance** Circular Frequency W [c.AMP] = 47,166.10^{15} Hz ≡ W [AN-CIS] .

This Property of Synapses allows to Antidotes to be helped by other indivisual Atoms .

7...SYNAPSES = **THE PHYSICAL EQUIVALENT OF MAGNETS .**

The Animated diagram is showing the Operation of a tuned circuit (The LC circuit). The capacitor C stores Energy in its Electric field *E* and the inductor L stores Energy in its Magnetic field *B (green)*. The animation shows the circuit at progressive points in the oscillation. The oscillations are slowed down; in an actual tuned circuit the charge may oscillate back and forth Thousands to Billions of times per second.



Intensity Current $\left[I(t) = Q_0 \omega \sin(\omega t) \right]$

Remarks :

a).. EU-Cisplatin-3 Interacts , by Coupling its Electrical-Resonator which is a tuned circuit storing Energy , and oscillating at the Synapses-Cell`scircuit`s Resonant frequency .

b).. The storing energy of , Antidote`s LC- circuit = **Drug Cisplatin** , flows to the Synapses Cell`s LC-circuit , in a Period $T / 4 = 33{,}33837 \cdot 10^{-18}$ s ,

c).. This tank of energy is **The circuit current** $I_0 = \rightarrow$ **1,4731221** Ampere which is charging the empty tank and after it **discharging .**

d).. From Program is seen that all Cisplatin-Elements are FREE and can **separately Act** on the corresponding Synapses Cell`s LC-circuit , In essence, frequency-coupling describes how the behavior of oscillating frequencies is influenced by their interaction with each other, and leading to various Phenomena and Applications across diverse and Spread fields as are the Isolated Atoms .

The *Demodulating from the Athwart - Spread Energy Vibrating Spectrum*]

e).. The case of Drugs enters in the Grid-tied converters where , The storing Energy of , **Antidotes LC-circuit ⇒ Drug** , flows to the **CELL`s LC - circuit** .

f).. **Generally** , all Interactions at Resonance circular – frequencies , W [1] → W [2] → W [n] follow the Grid-tied converters and in Program → [***The Athwart - Spread Energy Vibrating Spectrum***] , where the Energy = motion in LC – Circuit (1) from its Resonance circular frequency W [1] , **flows to** → W [2] circular frequency through LC – Circuit(2) which occupy the same Voltage as $[V_1 \times i_1] \cos(\varphi) = [V_2 \times i_2] \cos(\varphi)$, where , **φ** , is the Phase of the two circular frequencies .

g).. The continous Supply with the Drug **Cisplatin** Kills the cancerd **Cells** .

z

THE CHEMO MECHANICAL COUPLING :.

EU-Cisplatin-3 for Chemotherapy has the chemical Strructrure → 262.[N_2 P_t O_3]
The Modulated and Cancered Breast Resonance frequency was found as below ,
$W_{MO-D} = 47{,}0513.10^{15}$ Hz , while the Cisplatin`s Drug Antidote was checked from Program and is $\mathbf{W_{AN-CIS} = 47{,}1513.10^{15}\ Hz}$ .with Energy $Q_0 = h\,f = h\,.\,\frac{W_{AN-CIS}}{2\pi}$

$= 6{,}626.10^{-34}$ J.s $[\frac{47{,}1513.10^{15}\ Hz}{2\pi}] = \mathbf{312{,}4245.10^{-19}\ J}$ s/s = **Joule** .

1...Drug Cisplatin-3 = The **Antidote LC-circuit-coupling** becomes from equation

$LC = [\frac{1}{W_{AN-CIS}}]^2 \equiv [\frac{1}{47{,}0513.10^{15}}]^2 = \mathbf{4{,}49793.10^{-34}\ HF = F/s}$

2...From Energy conservation $I_0 = \sqrt{\frac{1}{LC}}\,.\,Q_0 = W_{AN-CIS}\cdot Q_0 = 47{,}1513.10^{15}$Hz .

$312{,}4245.10^{-19}$ J = $14731{,}221.10^{-4}$ Ampere = **1,4731221 Ampere**

3... Accepting inductance $\mathbf{L = 1.10^{-19}\ Hz}$ then capacity , $C = \frac{1}{L}.[\frac{1}{W_{AN-CIS}}]^2$ and

equal to $C = \frac{1}{10^{-19}}\ 4{,}49793.10^{-34} = \mathbf{4{,}49793.10^{-15}\ Farad}$

Resonance-Voltage $= \frac{Work}{Capacity} = \frac{Q_0}{C} = \frac{312{,}4245.10^{-19}\ J}{4{,}49793.10^{-15}\ F} = 69{,}459618.10^{-4}$ Volt

$= \mathbf{69{,}459618.10^{-4}\ Volt = 6{,}9459618\ (m\text{-}Volt)}$. The Power of the **R-System** is P_{LC} = Voltage .Ampere = $V_L\,.\,I_0 = 69{,}459618.10^{-4}$ Volt x 1,4731221 A =

$102{,}32249.10^{-4}$ Watt $= \mathbf{0{,}10232249\ Watt = 10{,}232249\ (m\text{-}Watt)}$

4... The Voltage across the Inductor is → $V_L = L\,.\,W_{AN-CIS}\cdot Q_0\,.\,\sin(\omega t + \varphi)$, and max. $\mathbf{V_L = L.[\,W_{AN-CIS}\cdot Q_0 = I_0\,] = L\,.\,I_0} = 10^{-19}$ Hz .1,4731221 Ampere = $1{,}4731221.10^{-19}$Hz. A = $1{,}473122.10^{-19}$ /1,6022. 10^{-19} e-Volts = **0,919437. eV**

5... The **maximum flowing** current becomes from equal equation $L\,i_0^{\,2}/2 = i_0^{\,2}/C$

where then , $i_0 = \sqrt{\frac{1}{LC}}\cdot q_0 = W_{AN-CIS}\cdot q_0 = 47{,}15.10^{15}$ Hz.[$312{,}4245.10^{-19}$J] =

$14731{,}221.10^{-4}$ Ampere = **1,4731221 A = Ampere**

6...The Capacity becomes complete discharged at Period T / 4 → 90 ° and is ,

$T/4 = \frac{2\pi}{w}[\frac{1}{4}] = 0{,}0333837.10^{-15} = 33{,}33837.10^{-18}$ s

7...***The Program can immediately Dedect and Represent the Resonated-Antidotes to Any Chemomechanical Coupling .***

Conclusion :

EU-Cisplatin-3 Interacts , by Coupling its Electrical-Resonator which is a ***tuned circuit*** storing Energy , and oscillating at the Cell`s circuit`s resonant frequency .
Thus the storing energy of , Antidote`s LC- circuit = **Drug Cisplatin** , flows to the **SYNAPSES** Cell`s LC-circuit . This tank of energy is → **1,4731221** Ampere and charged Discharged in $33{,}33837.10^{-18}$ s.
A continous supply with the Drug Cisplatin Kills the cancerd Cells .

Compound — APPLICATION-1

Description	8-1= NEW ANTICANCER Gisplatin = 240.[N2 Pt Cl2 F H6]
Formula	$N_{480}Pt_{240}Cl_{480}F_{240}H_{1440}$
Total Number of Elements	2880
Stiffness Factor	1440

ANTIPOTE Detected from GOOGLE
